

# Welcome

Thank you for choosing Freenove products!

## How to Start

First, read the document **Read Me First.pdf** in the unzipped folder.

If you did not download the zip file, please download it and unzip it.

## Get Support & Customer Service

You may find somethings missing or broken, or some difficulty to learn the kit.

Freenove provides free and quick support, including but not limited to:

- Quality problems of products
- Problems in using products
- Questions for learning and technology
- Opinions and suggestions
- Ideas and thoughts

If you have any concerns, please send email to us:

**[support@freenove.com](mailto:support@freenove.com)**

And suggestions and feedbacks are welcomed. Many customers offered great feedbacks. According to that, we are keeping updating the kit and the tutorial to make it better. Thank you.

## Safety

Pay attention to safety when using and storing this product:

- Do not expose children under 6 years of age to this product. Put it out of their reach.
- Children lack safety ability should use this product under the guardianship of adults.
- This product contains small and sharp parts. Do not swallow, prick and scratch to avoid injury.
- This product contains conductive parts. Do not hold them to touch power supply and other circuits.
- Some parts will rotate or move when it works. Do not touch them to avoid being bruised or scratched.
- The wrong operation may cause overheat. Do not touch and disconnect the power supply immediately.
- Operate in accordance with the requirements of the tutorial. Otherwise, the parts may be damaged.
- Store the product in a dry place and avoid direct sunlight.
- Turn off the power of the circuit before leaving.

## About

Freenove provides open source electronic products and services.

Freenove is committed to helping customers learn programming and electronic knowledge, quickly realize their creative ideas and product prototypes and launching innovative products. Our services include:

- Kits of robots, smart cars and drones
- Kits for learning Arduino, Raspberry Pi and micro:bit
- Electronic components and modules, tools
- **Product customization service**

You can learn more about us or get our latest information through our website:

<http://www.freenove.com>

## Copyright

All the files we provided are released under [Creative Commons Attribution-NonCommercial-ShareAlike 3.0 Unported License](#). You can find a copy of the license in the folder.

This means you can use them on your own derived works, in part or completely. But NOT for the purpose of commercial use.

Freenove brand and logo are copyright of Freenove Creative Technology Co., Ltd. Cannot be used without formal permission.

# Preface

Raspberry Pi is a low cost, **credit-card sized computer** that plugs into a computer monitor or TV, and uses a standard keyboard and mouse. It is a capable little device that enables people of all ages to explore computing, and to learn how to program in languages like Scratch and Python. It's capable of doing everything you'd expect a desktop computer to do, from browsing the internet and playing high-definition video, to making spreadsheets, word-processing, and playing games. For more information, you can refer to Raspberry Pi official [website](#). We will call it RPi, RPI, RasPi later in this tutorial.

In this tutorial, the most chapters are consist of **Components List**, **Component Knowledge**, **Circuit**, and **Code** (**C** code and **Python** code). We provide both C and Python code for each project in this tutorial. After completing this tutorial, you can learn Java by reading Processing.pdf.

The supporting kit contains the accessory electronic components and modules needed to complete these projects. You can also use these components and modules to achieve your own creativity.

Additionally, if you have any difficulties or questions about this tutorial and the kit, you can always contact us for quick and free support:

**[support@freenove.com](mailto:support@freenove.com)**

# Raspberry Pi

So far, Raspberry Pi has developed to the fourth generation. Changes in versions are accompanied by increase and upgrades in hardware.

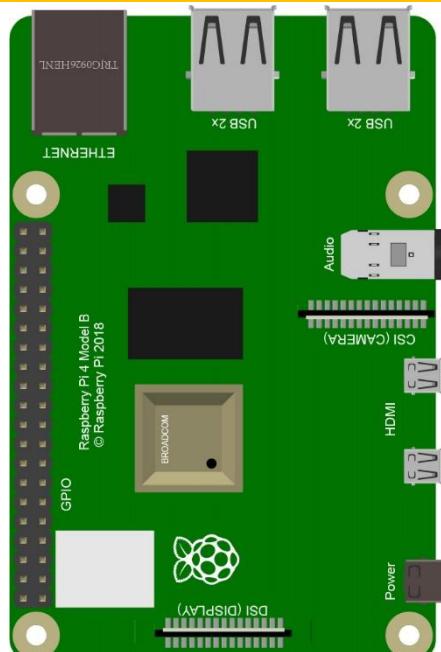

A type and B type, the first generation of products, have been stopped due to various reasons. Other versions are popular and active and the most important is that they are consistent in the order and number of pins, which greatly enhances the compatibility of peripheral devices between different versions.

Below are the raspberry pi pictures and model pictures supported by this product. They have 40 pins.

Practicality picture of Raspberry Pi 4 Model B:

Hardware interface diagram of RPi Zero/Zero W is shown below:

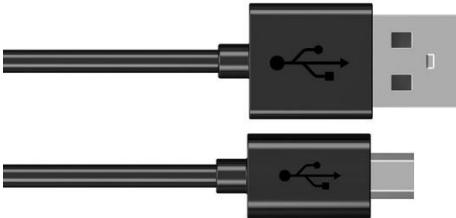

# Install the System

Firstly, install a system for your RPi.

## Component List

### Required Components

Any Raspberry Pi	5V/3A Power Adapter. Different versions of Raspberry Pi have different power requirements.
	
Micro or Type-C USB Cable x1	Micro SD Card(TF Card)x1, Card Reader x1
	

Power requirement of different versions of Raspberry Pi is shown in following table:

Product	Recommended PSU current capacity	Maximum total USB peripheral current draw	Typical bare-board active current consumption
Raspberry Pi Model A	700mA	500mA	200mA
Raspberry Pi Model B	1.2A	500mA	500mA
Raspberry Pi Model A+	700mA	500mA	180mA
Raspberry Pi Model B+	1.8A	600mA/1.2A (switchable)	330mA
Raspberry Pi 2 Model B	1.8A	600mA/1.2A (switchable)	350mA
Raspberry Pi 3 Model B	2.5A	1.2A	400mA
Raspberry Pi 3 Model A+	2.5A	Limited by PSU, board, and connector ratings only.	350mA
Raspberry Pi 3 Model B+	2.5A	1.2A	500mA
Raspberry Pi 4 Model B	3.0A	1.2A	600mA
Raspberry Pi Zero W	1.2A	Limited by PSU, board, and connector ratings only.	150mA
Raspberry Pi Zero	1.2A	Limited by PSU, board, and connector ratings only	100mA

For more details, please refer to <https://www.raspberrypi.org/help/faqs/#powerReqs>

In addition, RPi also needs a network cable used to connect it to wide area network.

All these components are necessary. Among them, the power supply is required at least 5V/2.5A. Because a lack of power supply may lead to many abnormal problems and even damage to your RPi. So power supply with 5V/2.5A is highly recommend. SD Card Micro (recommended capacity 16GB or more) is a hard drive for RPi, which is used to store the system and personal files.

## Optional Components

Under normal circumstances, there are two ways to login to Raspberry Pi: using independent monitor or remote desktop to share a monitor with your PC.

### Required Accessories for Monitor

If you want to use independent monitor, mouse and keyboard, you also need the following accessories.

- 1.Display with HDMI interface
- 2.Mouse and Keyboard with USB interface

As to Pi Zero and Pi Zero W, you also need the following accessories.

1. Mini-HDMI to HDMI converter&wire.
2. Micro-USB to USB-A Receptacles converter&wire (Micro USB OTG wire).
3. USB HUB.
4. USB transferring to Ethernet interface or USB Wi-Fi receiver.

For different Raspberry Pi, the optional items are slightly different. But they all aim to convert the special interface to standard interface of standard Raspberry Pi.

	Pi Zero	Pi A+	Pi Zero W	Pi 3A+	Pi B+/2B	Pi 3B/3B+	Pi 4B
<b>Monitor</b>				Yes			
<b>Mouse</b>				Yes			
<b>Keyboard</b>				Yes			
<b>Mini-HDMI to HDMI converter or wire</b>	Yes	No	Yes	No	No	No	No
<b>Micro-HDMI to HDMI converter &amp; wire</b>				No			Yes
<b>Micro-USB to USB-A Receptacles converter &amp; wire (Micro USB OTG wire)</b>	Yes	No	Yes			No	
<b>USB HUB</b>	Yes	Yes	Yes	Yes	No	No	
<b>USB transferring to Ethernet interface</b>	select one from two or select two from two			optional	Internal Integration	Internal Integration	
<b>USB Wi-Fi receiver</b>							

## Required Accessories for Remote Desktop

If you don't have an independent monitor, or if you want to use a remote desktop, first you need to login to Raspberry Pi through SSH, then open the VNC or RDP service. So you need the following accessories.

	Pi Zero	Pi Zero W	Pi A+	Pi 3A+	Pi B+/2B	Pi 3B/3B+/4B
<b>Micro-USB to USB-A Receptacles converter&amp;wire (Micro USB OTG wire)</b>	Yes	Yes	No			NO
<b>USB transferring to Ethernet interface</b>	Yes	Yes	Yes			

## Raspbian System

### Official Method (Recommended)

You can follow the official method to install the system for raspberry pi via visiting link below:

<https://projects.raspberrypi.org/en/projects/raspberry-pi-setting-up/2>

In this way, the system will be download **automatically** via the application.

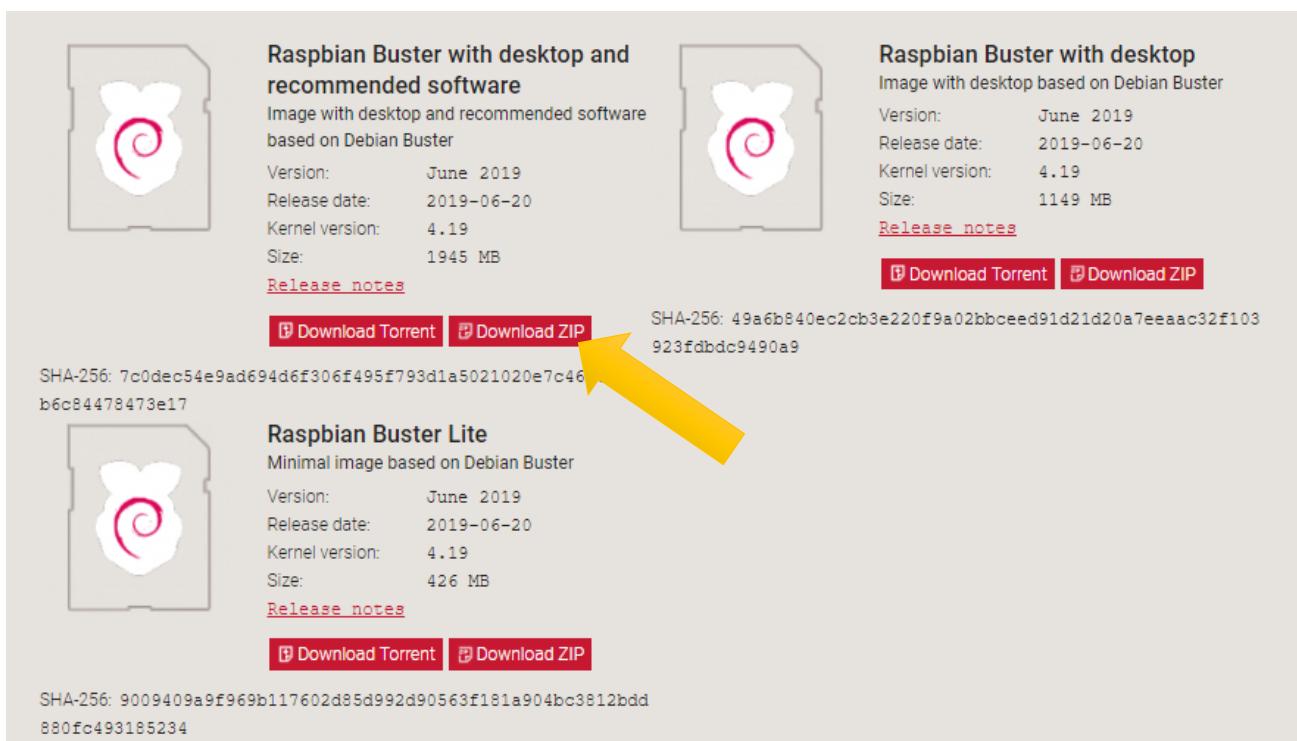

#### Download system manually (optional)

After installing the Image Tool in **link above**. You can also download the system **manually** first.

Visit RPi official website (<https://www.RaspberryPi.org/>), click “Downloads” and choose to download “RASPBIAN”. RASPBIAN supported by RPI is an operating system based on Linux, which contains a number of contents required for RPi. We recommended RASPBIAN system to beginners. All projects in this tutorial are operated under the RASPBIAN system.

The screenshot shows the "Downloads" section of the Raspberry Pi website. It features two main options: "NOOBS" (represented by a black square with a white Raspberry Pi logo) and "Raspbian" (represented by a white square with a red Linux logo). A large yellow arrow points from the text "Download it here, or use NOOBS, our easy installer for Raspbian and more." towards the Raspbian icon.

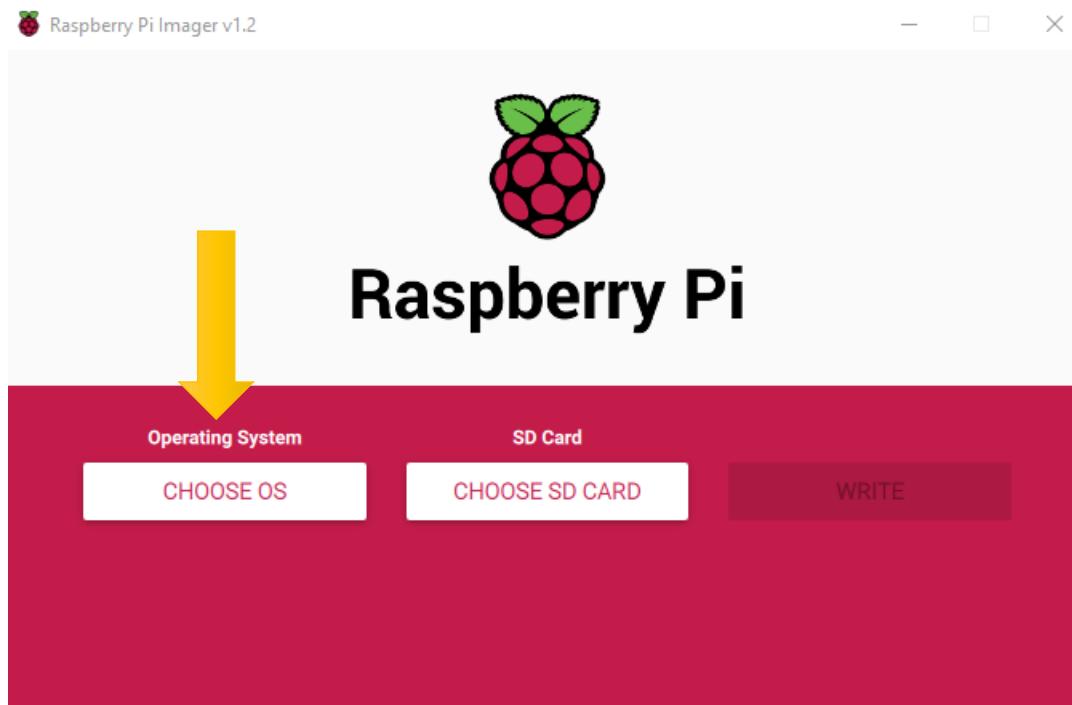

<https://www.raspberrypi.org/downloads/raspbian/>

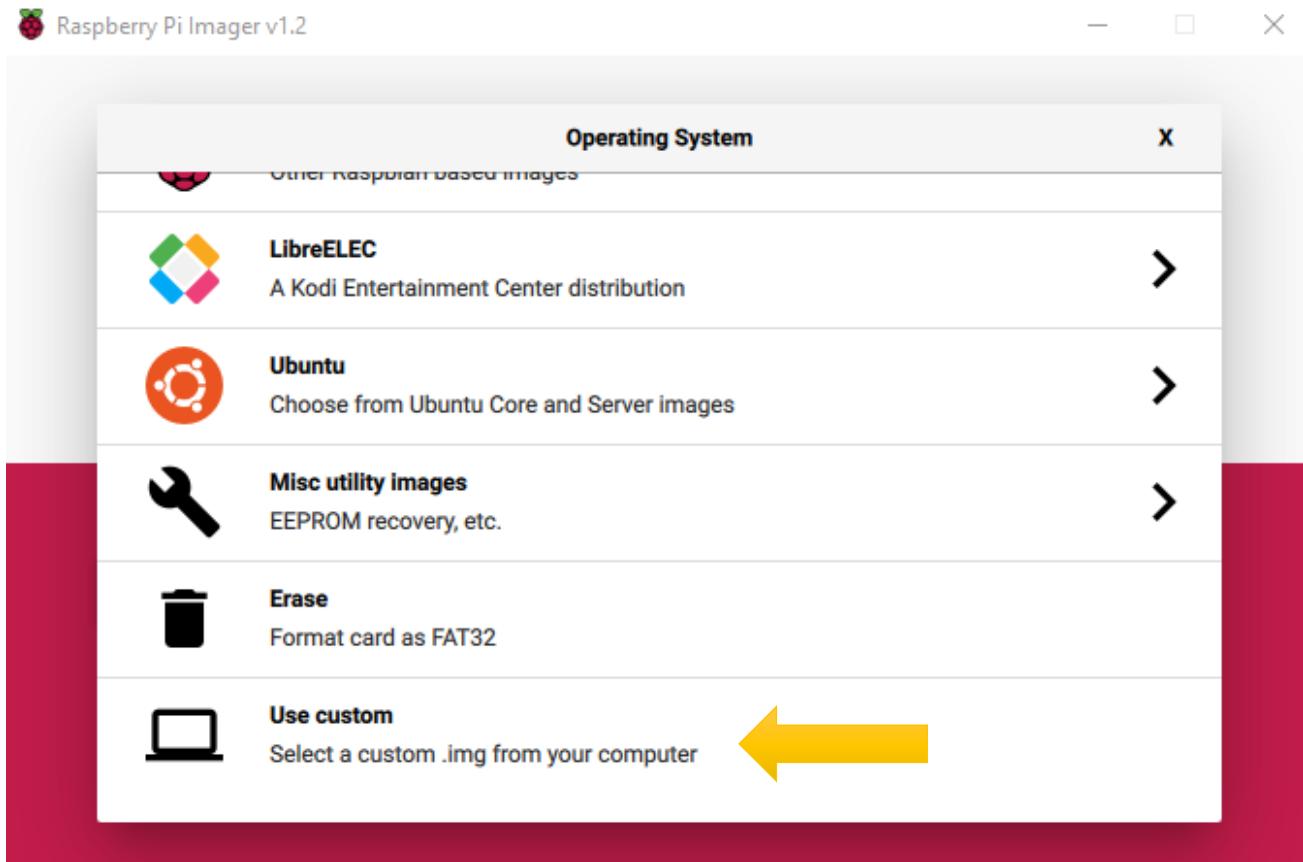

After the zip file is download.

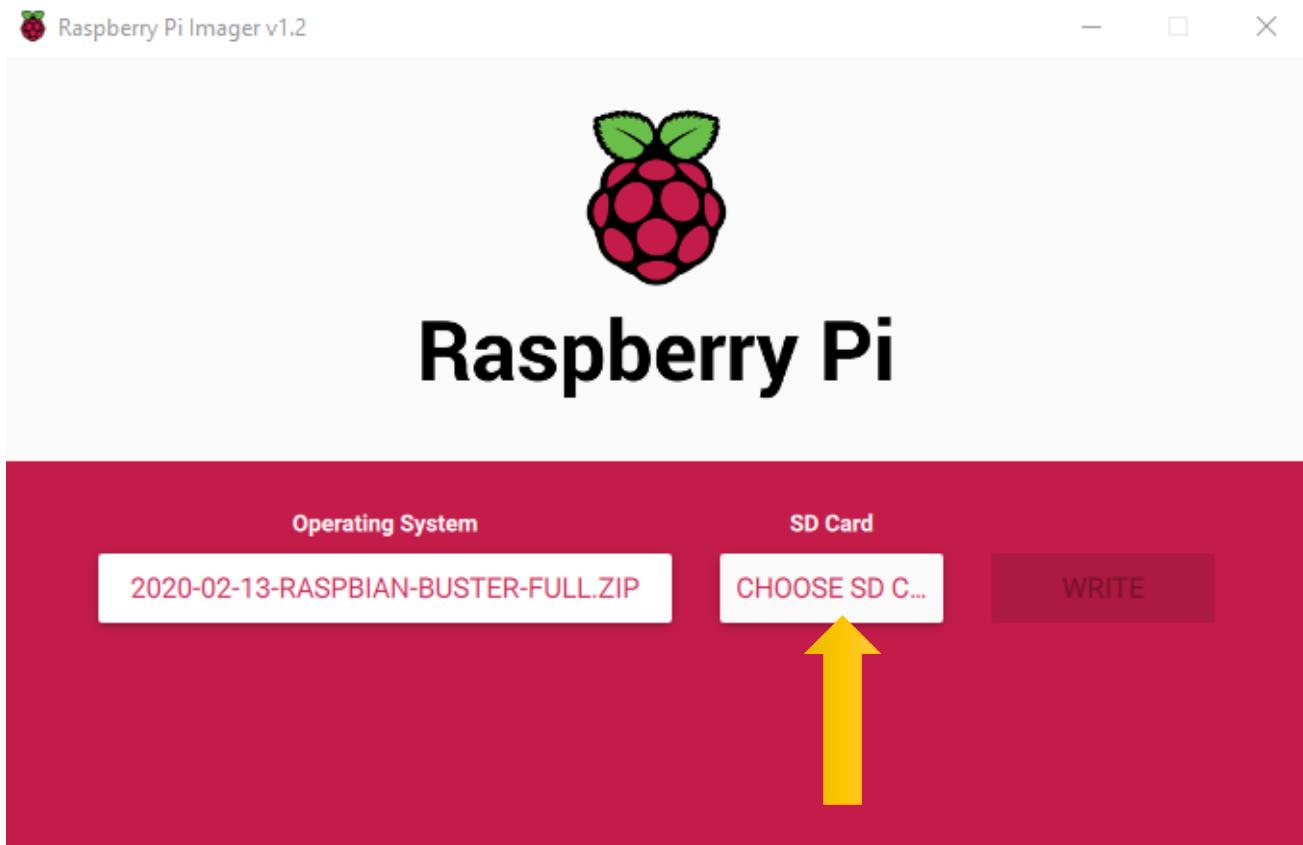

### Write System to Micro SD Card

First, put your Micro **SD card** into card reader and connect it to USB port of PC. Then open imager toll, choose Choose system that you just download in Usecustom.

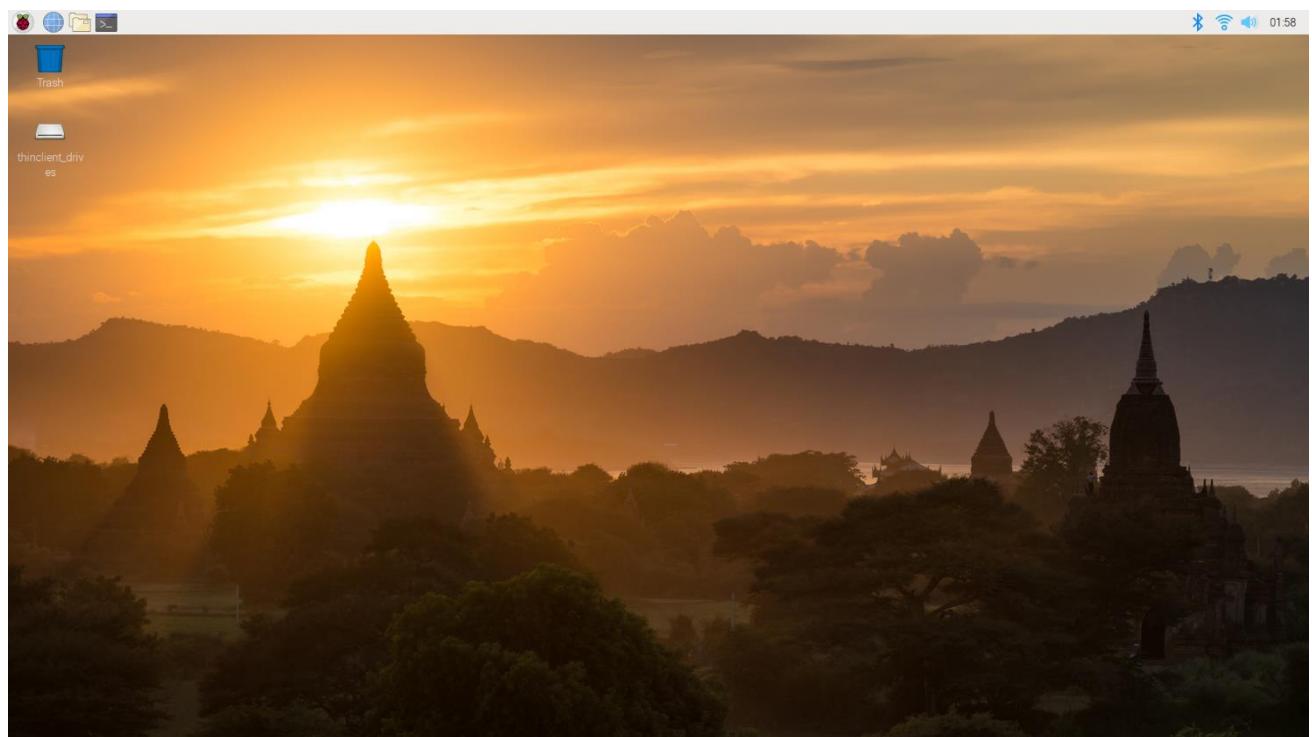

Choose the SD card. Then click "WRITE".

## Start Raspberry Pi

If you don't have a spare monitor, please jump to next section. If you have a spare monitor, please follow steps in this section.

After the system is written successfully, take out Micro SD Card and put it into the card slot of RPi. Then connect RPi to screen through the HDMI, to mouse and keyboard through the USB port, to network cable through the network card interface and to the power supply. Then your RPi will boot up. Later, you need to enter the user name and password to login. The default user name: pi; password: raspberry. Enter and login. After login, you can enter the following interface.

Now, you have successfully installed the RASPBIAN operating system for your RPi.

## Remote desktop & VNC

If you don't have a spare display, mouse and keyboard for your RPi, you can use a remote desktop to share a display, keyboard, and mouse with your PC. Below is how to use remote desktop to control RPi under the Windows operating system.

Under windows, Raspberry Pi can be generally accessed remotely through two applications. The first one is the windows built-in application remote desktop, which corresponds to the Raspberry Pi xrdp service. The second one is the free application VNC Viewer, which corresponds to the VNC interface of Raspberry Pi. Each way has its own advantages. You can choose either one or two.

Windows	Raspberry Pi
Remote Desktop Connection	Xrdp
VNC Viewer	VNC

VNC Viewer can not only run under Windows, but also under system MAC, Linux, IOS, Android and so on.

## SSH

Under previous Raspbian system, SSH is opened by default. Under the latest version of Raspbian system, it is closed by default. So you need to open it first.

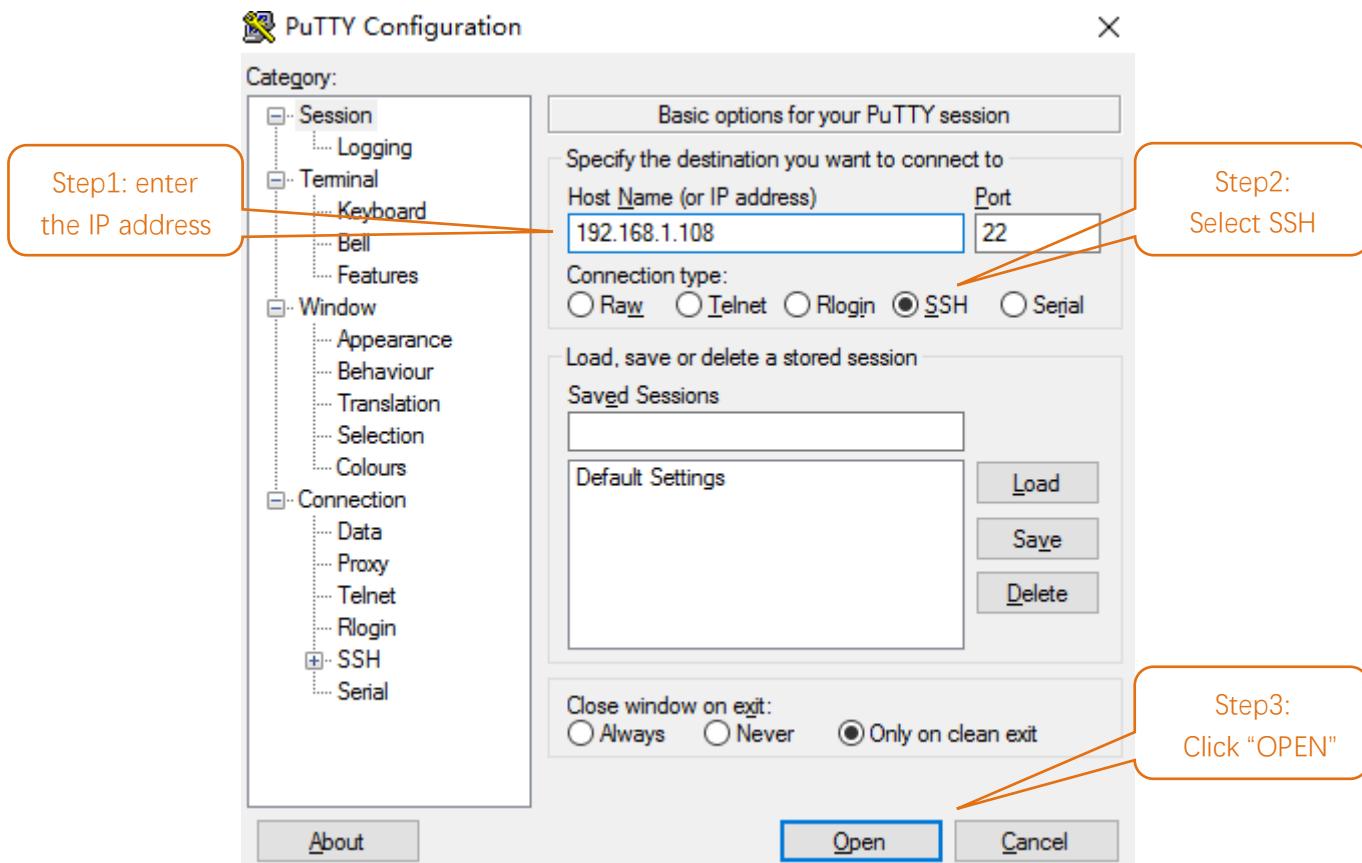

**Method: after the system is written, create a folder named “ssh” under generated boot disk, then the SSH connection will be opened.**

And then, download the tool software Putty. Its official address: <http://www.putty.org/>

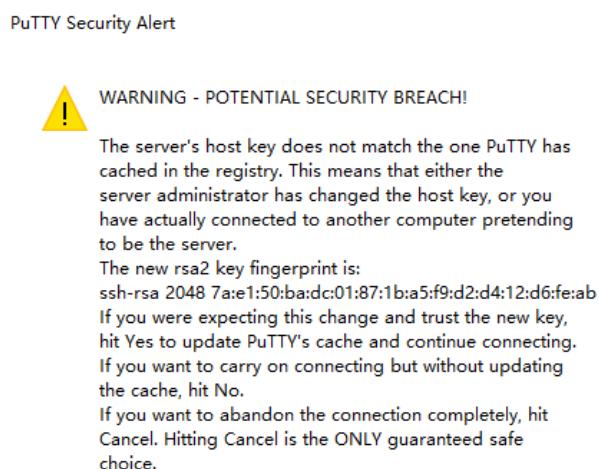

Or download it here: <http://www.chiark.greenend.org.uk/~sgtatham/putty/download.html>

Then use cable to connect your RPi to the routers of your PC LAN, and make sure your PC and your RPi in the same LAN. Then put the system Micro SD Card prepared before into the slot of the RPi and turn on the power supply waiting for RPi to start. Then find IP address named "raspberry pi" in router client.

For example, I have found my RPi IP address, and it is "192.168.1.108". Then open Putty, enter the address, select SSH, and then click "OPEN", as shown below:

There will appear a security warning at first login. Just click "YES".

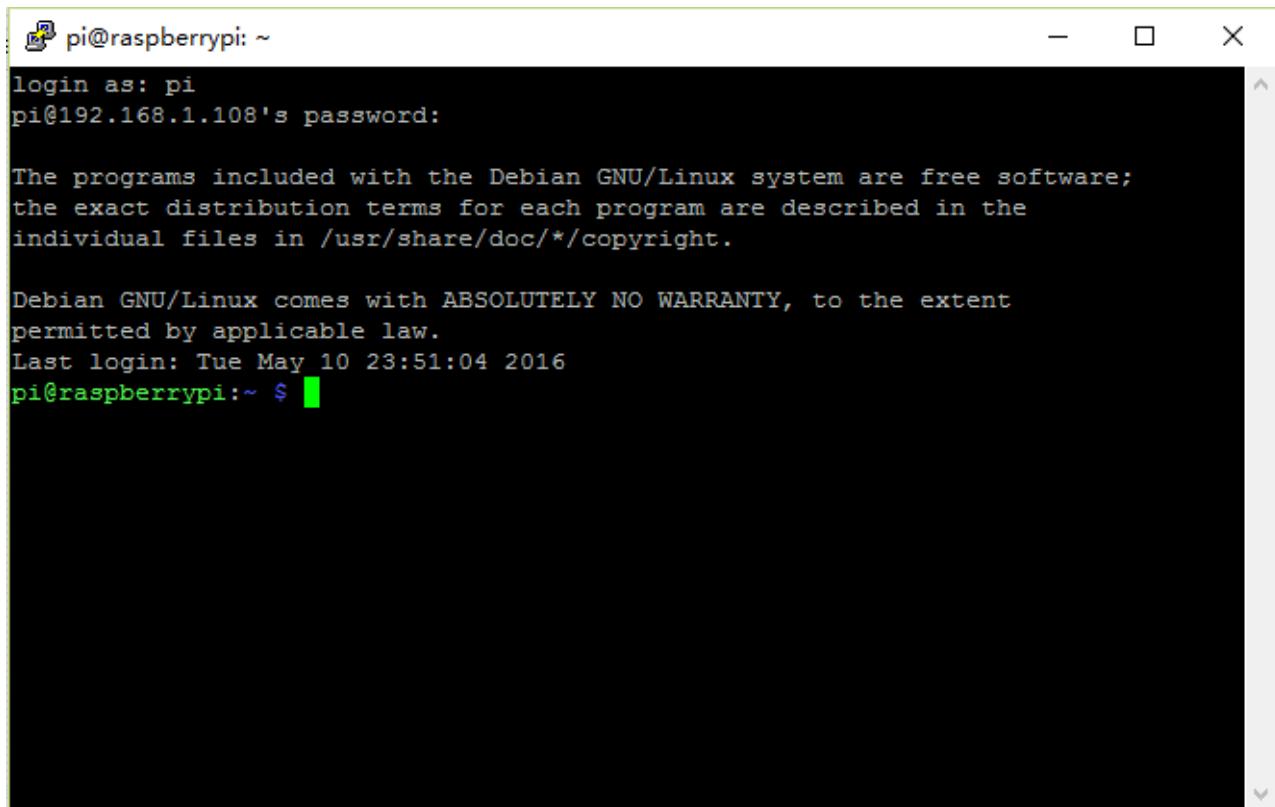

Then there will be a login interface (RPi **default user name: pi; the password: raspberry**). When you enter the password, there will be no display on the screen. This is normal. After the correct input, press “Enter” to confirm.

Then enter the command line of RPi, which means that you have successfully login to RPi command line mode.

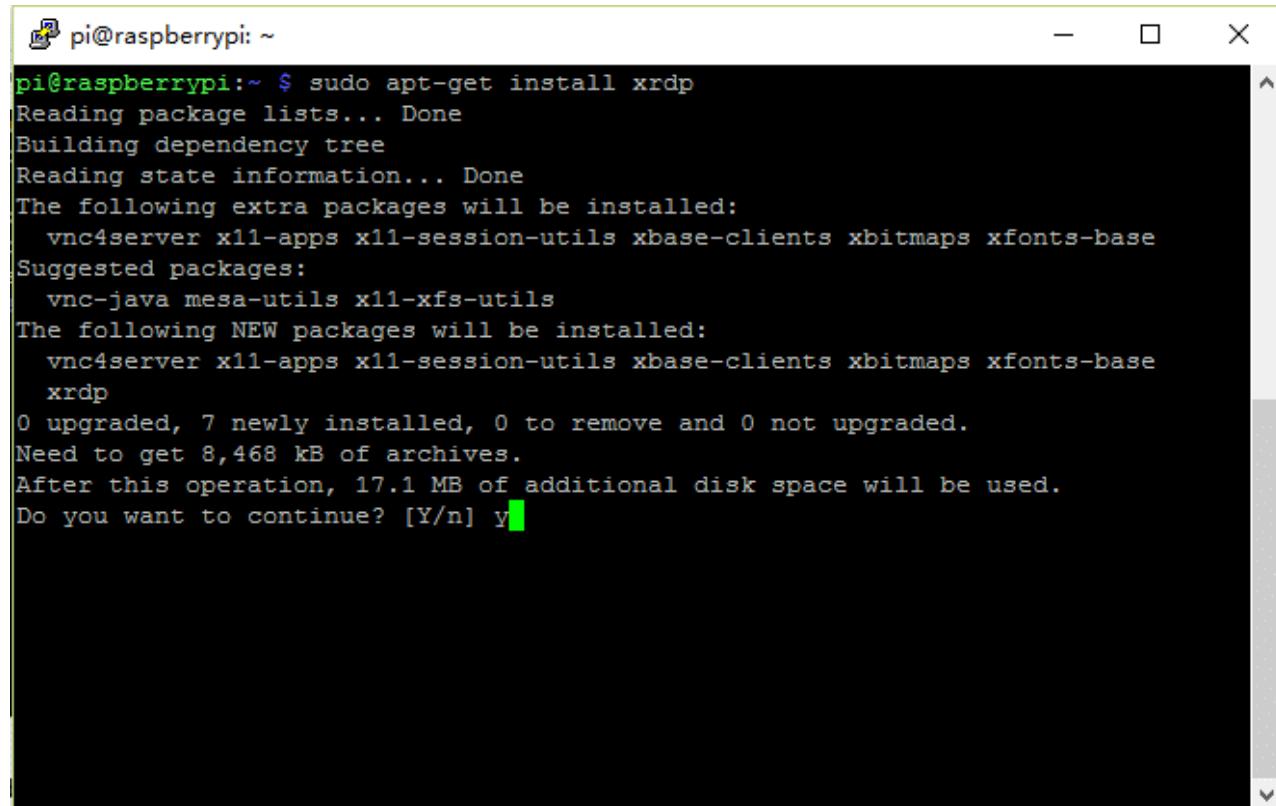

## Remote Desktop Connection & xrdp

If you want to use built-in Remote Desktop Connection under Windows, you need install xrdp service on RPi.

Next, install a xrdp service, an open source remote desktop protocol (rdp) server, for RPi. Type the command in the gray text box below, then press enter to confirm:

```
sudo apt-get install xrdp
```

Later, the installation starts.

A screenshot of a terminal window titled "pi@raspberrypi: ~". The window shows the command \$ sudo apt-get install xrdp being run. The terminal output includes package lists, dependency building, state information, extra packages to be installed (vnc4server, x11-apps, x11-session-utils, xbase-clients, xbitmaps, xfonts-base), suggested packages (vnc-java, mesa-utils, x11-xfs-utils), new packages to be installed (vnc4server, x11-apps, x11-session-utils, xbase-clients, xbitmaps, xfonts-base, xrdp), upgrade counts, archive sizes, disk space usage, and a prompt asking if the user wants to continue (Do you want to continue? [Y/n] y).

```
pi@raspberrypi:~ $ sudo apt-get install xrdp
Reading package lists... Done
Building dependency tree
Reading state information... Done
The following extra packages will be installed:
  vnc4server x11-apps x11-session-utils xbase-clients xbitmaps xfonts-base
Suggested packages:
  vnc-java mesa-utils x11-xfs-utils
The following NEW packages will be installed:
  vnc4server x11-apps x11-session-utils xbase-clients xbitmaps xfonts-base
  xrdp
0 upgraded, 7 newly installed, 0 to remove and 0 not upgraded.
Need to get 8,468 kB of archives.
After this operation, 17.1 MB of additional disk space will be used.
Do you want to continue? [Y/n] y
```

Enter "Y", press key "Enter" to confirm.

After the installation is completed, you can use Windows remote desktop applications to login to your RPi.

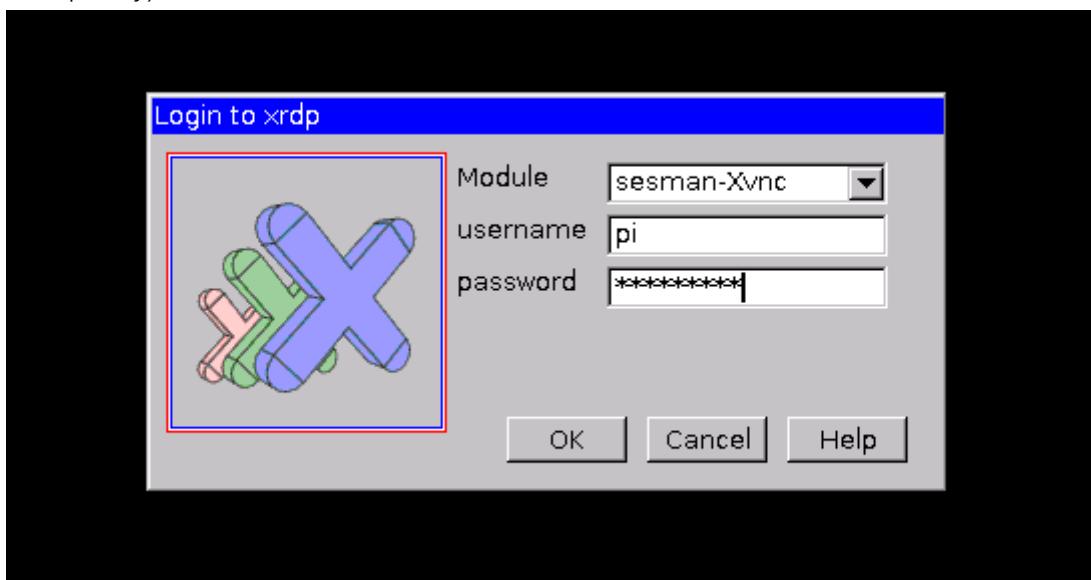

## Login to Windows remote desktop

Use "WIN+R" or search function, open the remote desktop application "mstsc.exe" under Windows, enter the IP address of RPi and then click "Connect".

Later, there will be xrdp login screen. Enter the user name and password of RPi (RPi default user name: pi; password: raspberry) and click "OK".

Later, you can enter the RPi desktop system.

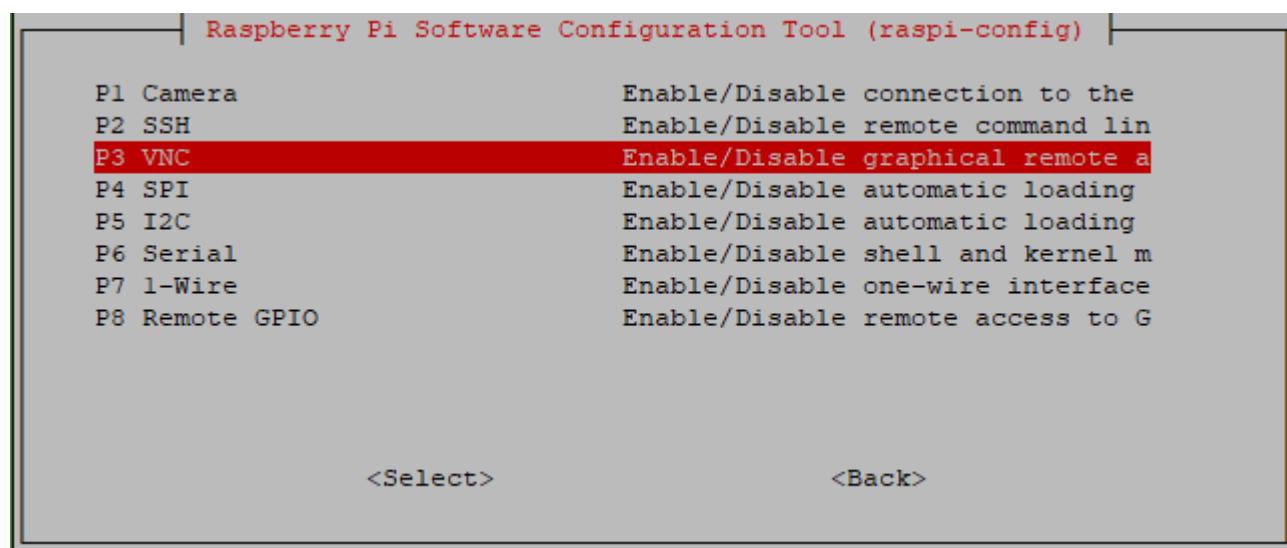

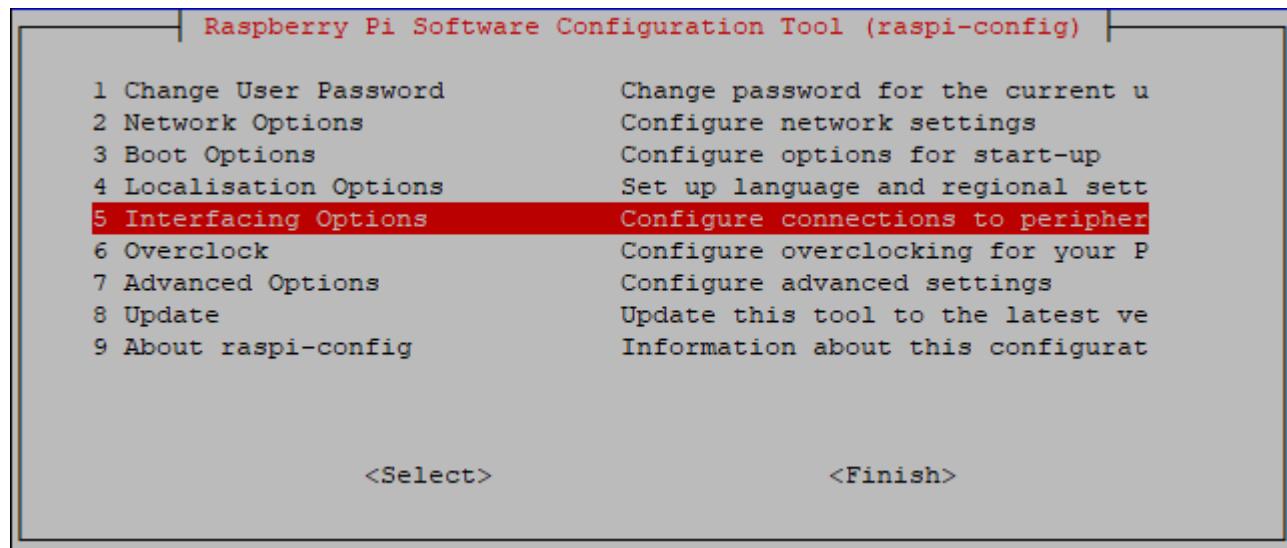

Here, you have successfully used the remote desktop login to RPi.

## VNC Viewer & VNC

Type the following command.

```
sudo raspi-config
```

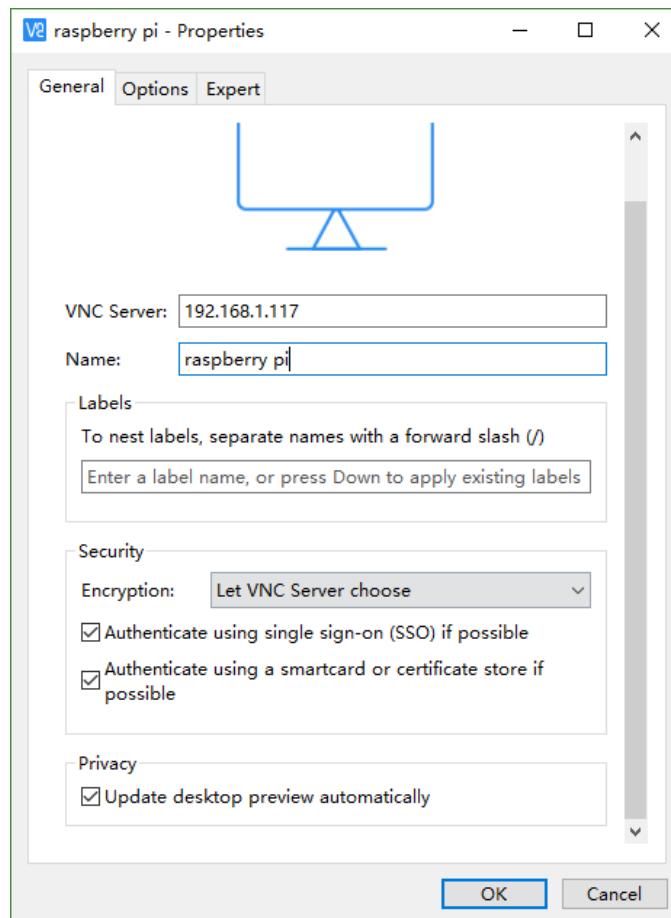

And select 5 Interfacing Options → P3 VNC → Yes → OK → Finish. Here Raspberry Pi may need be restarted, and choose ok. Then open VNC interface.

Then download and install VNC Viewer by click following link:

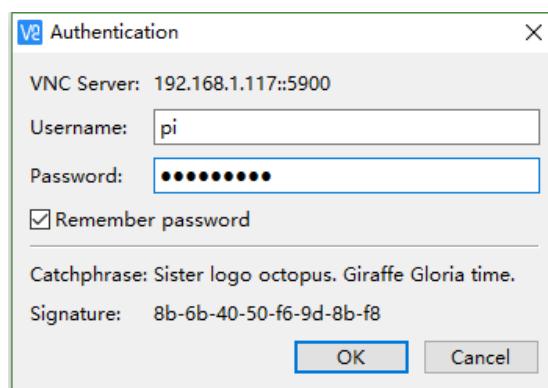

<https://www.realvnc.com/en/connect/download/viewer/windows/>

After installation is completed, open VNC Viewer. And click File → New Connection. Then the interface is shown below.

Enter ip address of your Raspberry Pi and fill in a Name. And click OK.

Then on the VNC Viewer panel, double-click new connection you just created, and the following dialog box pops up.

Enter username: pi and Password: raspberry. And click OK.

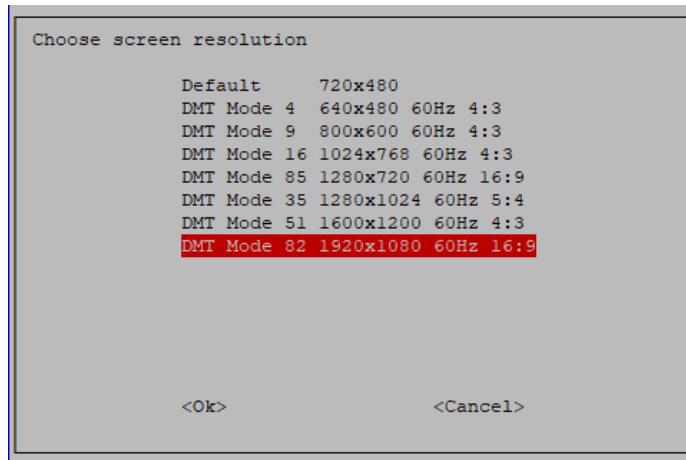

Here, you have logged in to Raspberry Pi successfully by using VNC Viewer

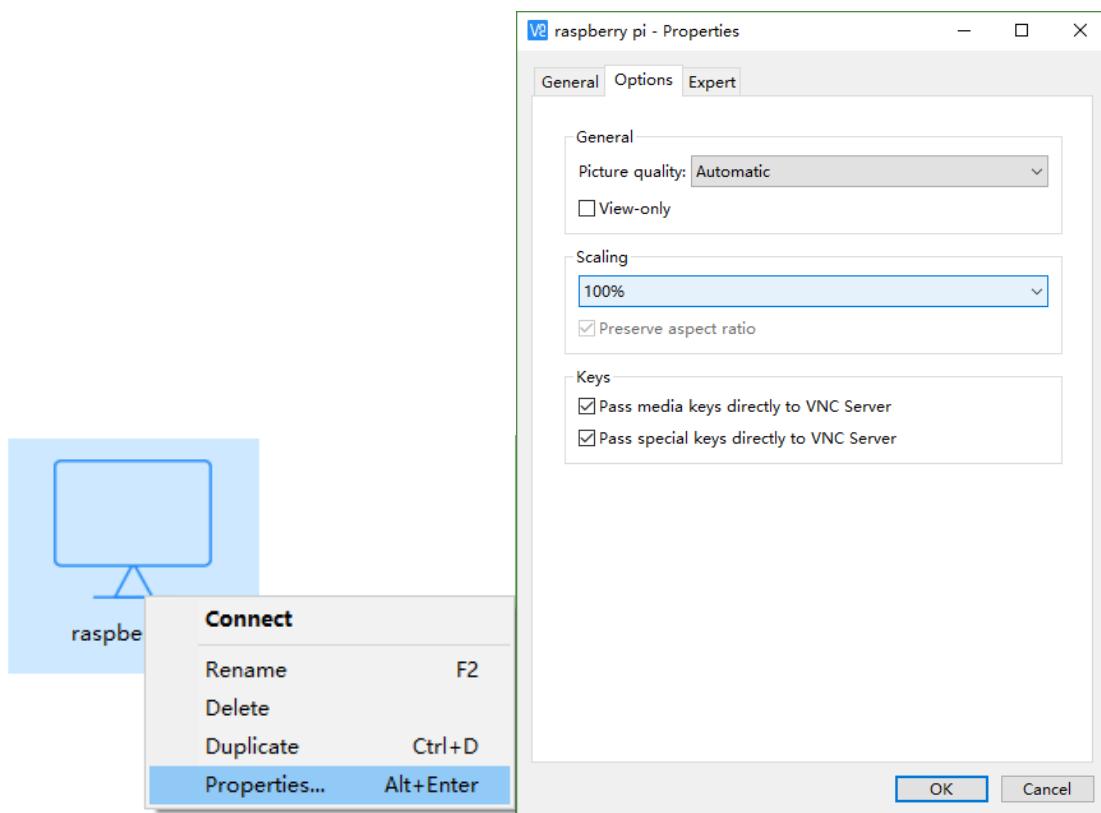

If the resolution ratio is not OK or there is just a **black little window**, you can set a proper resolution ratio via steps below.

```
sudo raspi-config
```

Select 7 Advanced Options → A5 Resolution → proper resolution ratio (set by yourself) → OK. If it needs restart, just restart.

In addition, your VNC Viewer window may zoom your Raspberry Pi desktop. You can change it. On your VNC View control panel, click right key. And select Properties -> Options label -> Scaling. Then set proper scaling.

Here, you have logged in to Raspberry Pi successfully by using VNC Viewer and operated proper setting. Then continue to do some preparation work: install a GPIO library wiringPi for your RPi.

## Wi-Fi

Raspberry Pi 4B, 3B+/3B integrates a Wi-Fi adaptor. You can use it to connect to your Wi-Fi. Then you can use the wireless remote desktop to control your RPi. This will be helpful for the following work. Raspberry Pi of other models can use wireless remote desktop through accessing an external USB wireless card.

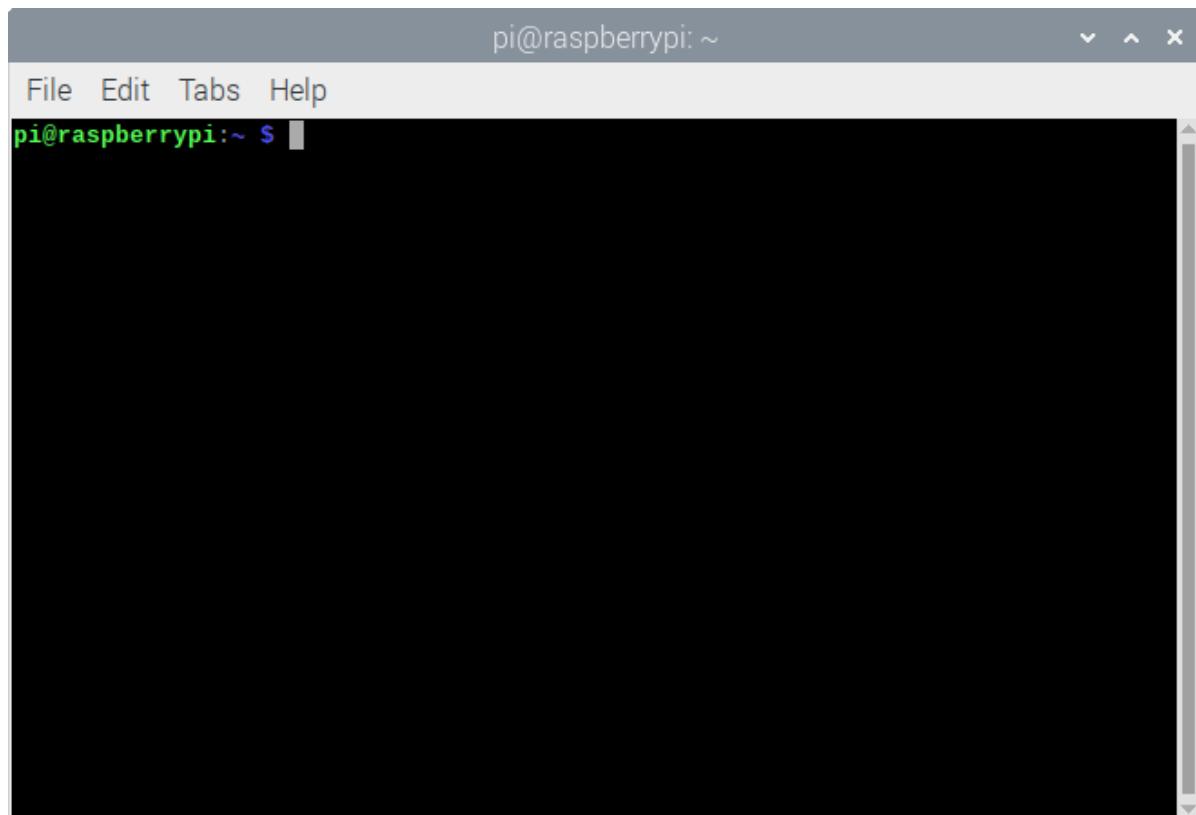

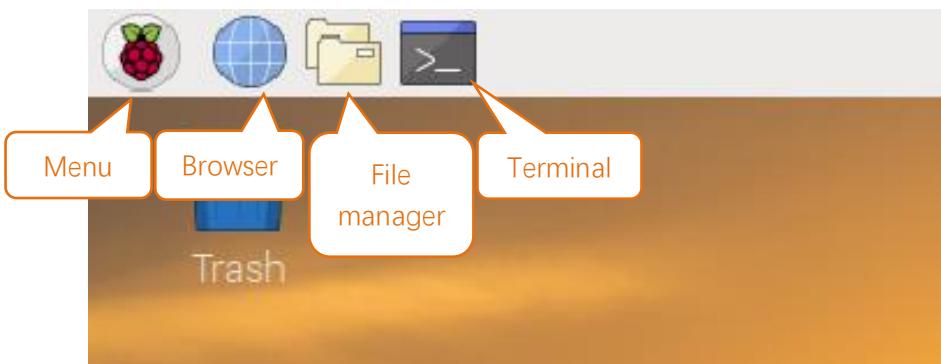

# Chapter 0 Preparation

Why this Chapter 0? In the program code, all the counts are starting from 0. So we choose to follow this rule. In this chapter, we will do some necessary preparation work: start your Pi Raspberry and install some necessary libraries. If your Raspberry Pi can be started normally and used normally, you can skip this chapter.

## Linux Command

Raspbian is based on Linux operation system. Now we will introduce some frequently-used Linux commands and usage methods.

First, open terminal. All commands are executed in terminal.

And the terminal is case sensitive.

Then type "ls" in terminal and press "Enter" key. The result is shown below:

```
pi@raspberrypi:~ $ ls
Desktop
Documents
Downloads
Freenove_Three-wheeled_Smart_Car_Kit_for_Raspberry_Pi
Freenove_Ultimate_Starter_Kit_for_Raspberry_Pi
MagPi
mu_code

Music
Pictures
Public
Templates
thinclient_drives
Videos
```

"ls", List information about the FILES (the current directory by default). Sort entries alphabetically.

Content between "\$" and "pi@raspberrypi:" is the current working path. "~" presents user directory. It is equal to "/home/pi" here. "pwd" can be used to view current working path.

```
pi@raspberrypi:~ $ pwd
/home/pi
```

"cd" is used to change directory. "/" presents root directory.

```
pi@raspberrypi:~ $ cd /usr
pi@raspberrypi:/usr $ ls
bin  games  include  lib  local  man  sbin  share  src
pi@raspberrypi:/usr $ cd ~
pi@raspberrypi:~ $
```

In later content, we will often change working path. Typing commands under the wrong directory may cause errors and break the execution of further commands. And the commands can not continue to be executed.

There are some frequently used commands and instructions in following table.

Command	instruction
<b>ls</b>	List information about the FILES (the current directory by default). Sort entries alphabetically.
<b>cd</b>	Change directory
<b>sudo + cmd</b>	Excute cmd under root authority
<b>./</b>	Under current directory
<b>gcc</b>	GNU Compiler Collection
<b>git clone URL</b>	Use git tool to clone the contents of specified repository, and URL is the repository address.

There are many commands later. For more details about command. You can refer to:

<http://www.linux-commands-examples.com>

### Shortcut Key

Now, we will introduce several shortcuts that are very useful and commonly used in terminal.

1. **up and down arrow keys.** History commands can be quickly brought back by using up and down arrow keys, which are very useful when you need to reuse certain commands.

When you need to type command, pressing “↑” will bring back the previous command, and pressing “↓” will bring back the latter command.

2. **Tab key.** The Tab key can automatically complete the command/path you want to type. When there are multiple commands/paths conforming to the already typed letter, pressing Tab key once won't have any result. And pressing Tab key again will list all the eligible options. This command/path will be directly completed when there is only one eligible option.

As shown below, under the '~' directory, enter the Documents directory with the "cd" command. After typing "cd D", press Tab key, then there is no response. Press Tab key again, then all the files/folders that begin with "D" is listed. Continue to type the character "oc", then press the Tab key, and then "Documents" is completed automatically.

```
pi@raspberrypi:~ $ cd D
Desktop/  Documents/ Downloads/
pi@raspberrypi:~ $ cd Doc
```

```
pi@raspberrypi:~ $ cd D
Desktop/  Documents/ Downloads/
pi@raspberrypi:~ $ cd Documents/
```

## Install WiringPi

WiringPi is a GPIO access library written in C for the BCM2835/BMC2836/ BMC2837 used in the Raspberry Pi. It's released under the GNU LGPLv3 license and is usable from C, C++ and many other languages with suitable wrappers (See below) It's designed to be familiar to people who have used the Arduino "wiring" system. (for more details, please refer to <http://wiringpi.com/> )

### WiringPi Installation Steps

New Raspbian system has integrated this library. So it may prompt that you have installed it.

Open the terminal. Follow these steps and commands to complete the installation.

For command with many lines, execute them line by line.

Enter the following command in the terminal to install WiringPi:

```
sudo apt-get update  
sudo apt-get upgrade  
sudo apt-get install wiringpi
```

As shown below, the installation will be completed soon.

```
pi@raspberrypi:~ $ sudo apt-get install wiringpi  
Reading package lists... Done  
Building dependency tree  
Reading state information... Done  
The following packages were automatically installed and are no longer required:  
  freetype2-doc rpi.gpio-common  
Use 'sudo apt autoremove' to remove them.  
The following NEW packages will be installed:  
  wiringpi  
0 upgraded, 1 newly installed, 0 to remove and 0 not upgraded.  
Need to get 0 B/52.9 kB of archives.  
After this operation, 0 B of additional disk space will be used.  
Selecting previously unselected package wiringpi.  
(Reading database ... 159071 files and directories currently installed.)  
Preparing to unpack .../wiringpi_2.50_armhf.deb ...  
Unpacking wiringpi (2.50) ...  
Setting up wiringpi (2.50) ...  
Processing triggers for man-db (2.8.5-2) ...
```

Run the gpio command to check the installation:

```
gpio -v
```

That should give you some confidence that it's working well.

```
pi@raspberrypi:~ $ gpio -v  
gpio version: 2.50  
Copyright (c) 2012-2018 Gordon Henderson  
This is free software with ABSOLUTELY NO WARRANTY.  
For details type: gpio -warranty  
  
Raspberry Pi Details:  
  Type: Unknown17, Revision: 01, Memory: 1024MB, Maker: Sony  
  * Device tree is enabled.  
  *--> Raspberry Pi 4 Model B Rev 1.1  
  * This Raspberry Pi supports user-level GPIO access.
```

## Obtain the Project Code

After the above work is done, you can visit our official website (<http://www.freenove.com>) or our github (<https://github.com/freenove>) to download the latest project code. We provide both **C** language and **Python** language code for each project in order to apply to user skilled in different languages.

Method for obtaining the code:

In the pi directory of the RPi terminal, enter the following command.

```
cd ~
```

```
git clone --depth 1 https://github.com/freenove/Freenove_Basic_Starter_Kit_for_Raspberry_Pi
```

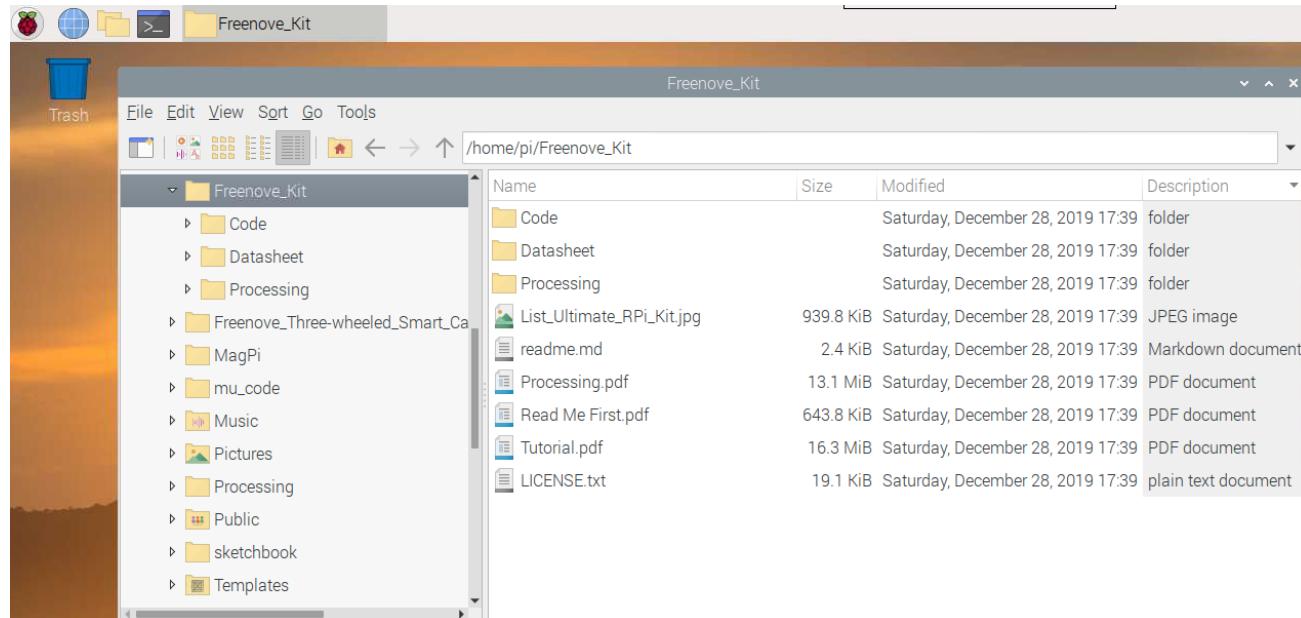

**(There is no need for password. If you get some errors, please check if your commands is correct.)**

After the download is complete, a new folder "Freenove\_Basic\_Starter\_Kit\_for\_Raspberry\_Pi" is generated, which contains all the tutorials and code.

The folder name is too long. Here we rename it by following command.

```
mv Freenove_Basic_Starter_Kit_for_Raspberry_Pi/ Freenove_Kit/
```

Among command above, "Freenove\_Kit" represents the new folder name. You can also rename the folder directly.

If you never learned anything of python, it is recommended to refer to follow website for basic knowledge.  
<https://python.swaroopch.com/basics.html>

## Python2 & Python3 (necessary)

If you only use C/C++, you can skip this section.

Now Python code of our kits can run on Python2 and Python3. **Python3 is recommended**. If you want to use python2, please make sure your Python version is above 2.7. Python2 and Python3 is not fully compatible.

You can type python2 and python3 in the terminal respectively to check if python has been installed. Press “**Ctrl+Z**” to exit.

```
pi@raspberrypi:~ $ python2
Python 2.7.13 (default, Nov 24 2017, 17:33:09)
[GCC 6.3.0 20170516] on linux2
Type "help", "copyright", "credits" or "license" for more information.
>>>
[2]+ Stopped python2
pi@raspberrypi:~ $ python3
Python 3.5.3 (default, Jan 19 2017, 14:11:04)
[GCC 6.3.0 20170124] on linux
Type "help", "copyright", "credits" or "license" for more information.
>>> █
```

Type python, and the terminal shows that it links to python2.

```
pi@raspberrypi:~ $ python
Python 2.7.13 (default, Nov 24 2017, 17:33:09)
[GCC 6.3.0 20170516] on linux2
Type "help", "copyright", "credits" or "license" for more information.
>>> █
```

**If you want to use editor Geany or Thonny, you need set Python3 as default Python first**, please follow the steps below.

1. Enter directory /usr/bin

```
cd /usr/bin
```

2. Delete the old python link.

```
sudo rm python
```

3. Create new python links to python3.

```
sudo ln -s python3 python
```

4. Execute python to check whether the link succeeds.

```
python
```

```
pi@raspberrypi:/usr/bin $ sudo rm python
pi@raspberrypi:/usr/bin $ sudo ln -s python3 python
pi@raspberrypi:/usr/bin $ python
Python 3.5.3 (default, Jan 19 2017, 14:11:04)
[GCC 6.3.0 20170124] on linux
Type "help", "copyright", "credits" or "license" for more information.
>>>
```

If you want to set python2 as default python, repeat above steps and just change the third command to the following.

```
sudo ln -s python2 python
```

```
pi@raspberrypi:/usr/bin $ sudo rm python
pi@raspberrypi:/usr/bin $ sudo ln -s python2 python
pi@raspberrypi:/usr/bin $ python
Python 2.7.13 (default, Nov 24 2017, 17:33:09)
[GCC 6.3.0 20170516] on linux2
Type "help", "copyright", "credits" or "license" for more information.
>>> 
```

Most code in our tutorial support python2 and python3.

For example, we will execute a same python file Hello.py with Python2 and Python3.

First, use Python2 to execute the code.

1. Use cd command to enter 00.0.0\_Hello directory of Python code.

```
cd ~/Freenove_Kit/Code/Python_Code/00.0.0_Hello
```

2. Use python2 command to execute python code Hello.py.

```
python2 Hello.py
```

```
pi@raspberrypi:~ $ cd Freenove_Kit/Code/Python_Code/00.0.0_Hello/
pi@raspberrypi:~/Freenove_Kit/Code/Python_Code/00.0.0_Hello $ python2 Hello.py
Hello World!
```

Use Python3 to execute the code under same directory.

3. Use python3 command to execute python code Hello.py.

```
python3 Hello.py
```

```
pi@raspberrypi:~ $ cd Freenove_Kit/Code/Python_Code/00.0.0_Hello/
pi@raspberrypi:~/Freenove_Kit/Code/Python_Code/00.0.0_Hello $ python3 Hello.py
Hello World!
```

As you can see, we get same results.

Because the code for our kit supports Python2 and Python3. We just say python later, not specific Python2 or Python3. You can choose python version according to your situation.

# Code Editor

This part is not necessary for later projects.

vi, nano, Geany

vi

Here we will introduce three kinds of code editor: vi, nano and Geany. Among them, nano and vi are used to edit files directly in the terminal. And Geany is an independent editing software, which is recommended for beginner. We will use the three editors to open an example code "Hello.c" respectively. First we will show how use vi and nano editor:

First, use cd command to enter the sample code folder.

```
cd ~  
cd ~/Freenove_Kit/Code/C_Code/00.0.0_Hello
```

Use the vi editor to open the file "Hello.c", then press ": q" and "Enter" to exit.

vi Hello.c

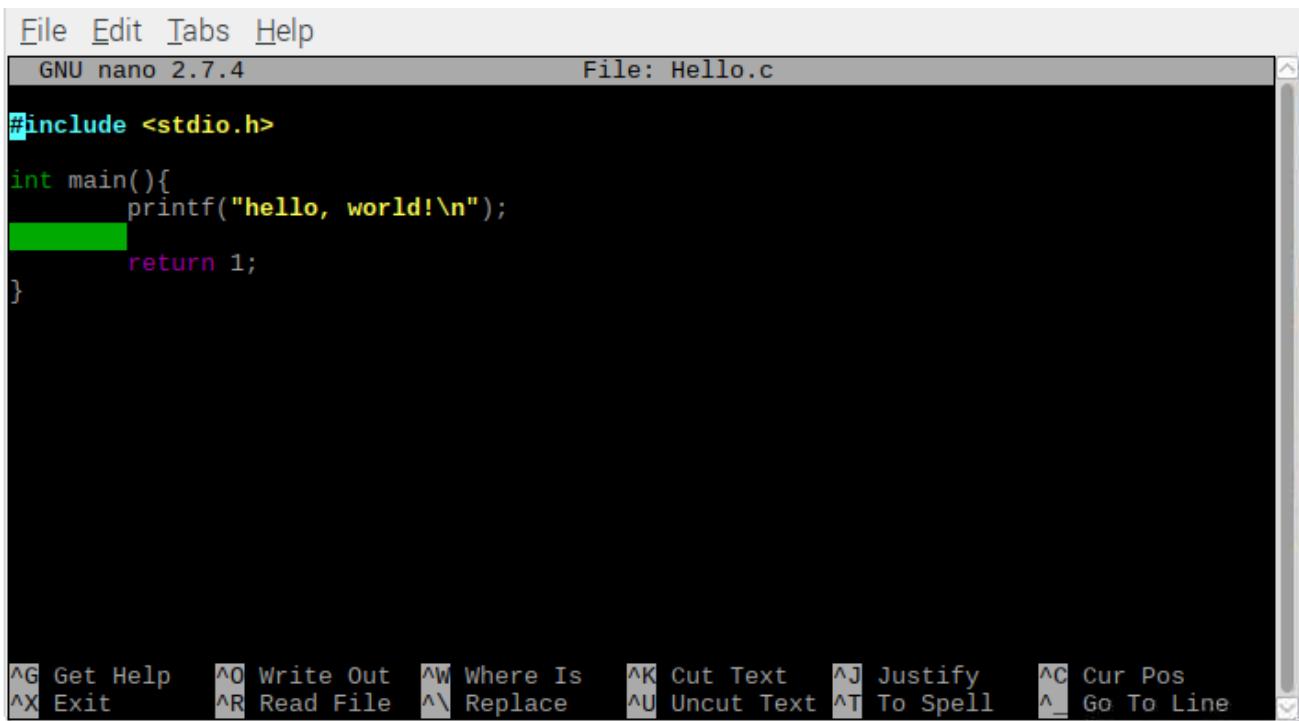

As is shown below:

nano

Use the nano editor to open the file "Hello.c", then press " Ctrl+X " to exit.

```
nano Hello.c
```

As is shown below:

The screenshot shows the nano text editor interface. The menu bar at the top includes File, Edit, Tabs, and Help. The title bar indicates "GNU nano 2.7.4" and "File: Hello.c". The main editing area contains the following C code:

```
#include <stdio.h>
int main(){
    printf("Hello, world!\n");
    return 1;
}
```

At the bottom of the screen, there is a toolbar with various keyboard shortcut keys for navigating and modifying the text.

Use the following command to compile the code to generate the executable file "Hello".

```
gcc Hello.c -o Hello
```

Use the following command to run the executable file "Hello".

```
sudo ./Hello
```

After the execution, "Hello, World!" is printed out in terminal.

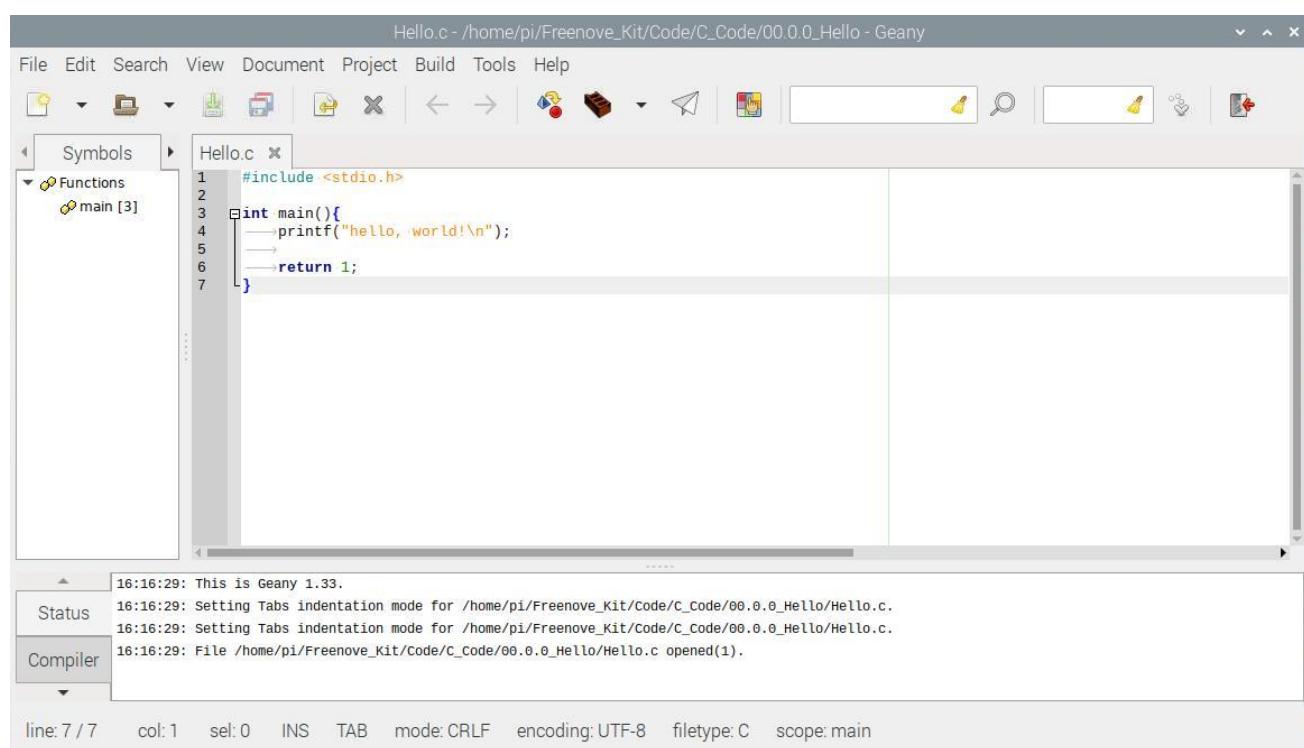

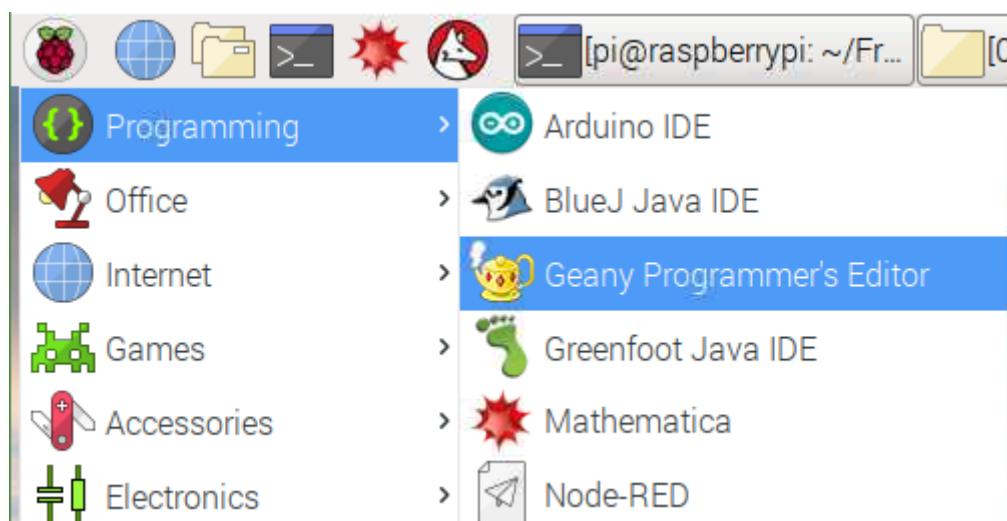

```
pi@raspberrypi:~/Freenove_Kit/Code/C_Code/00.0.0_Hello $ gcc Hello.c -o Hello
pi@raspberrypi:~/Freenove_Kit/Code/C_Code/00.0.0_Hello $ sudo ./Hello
Hello, world!
```

## Geany

Next, learn to use the Geany editor. Use the following command to open the Geany in the sample file "Hello.c" file directory path.

```
geany Hello.c
```

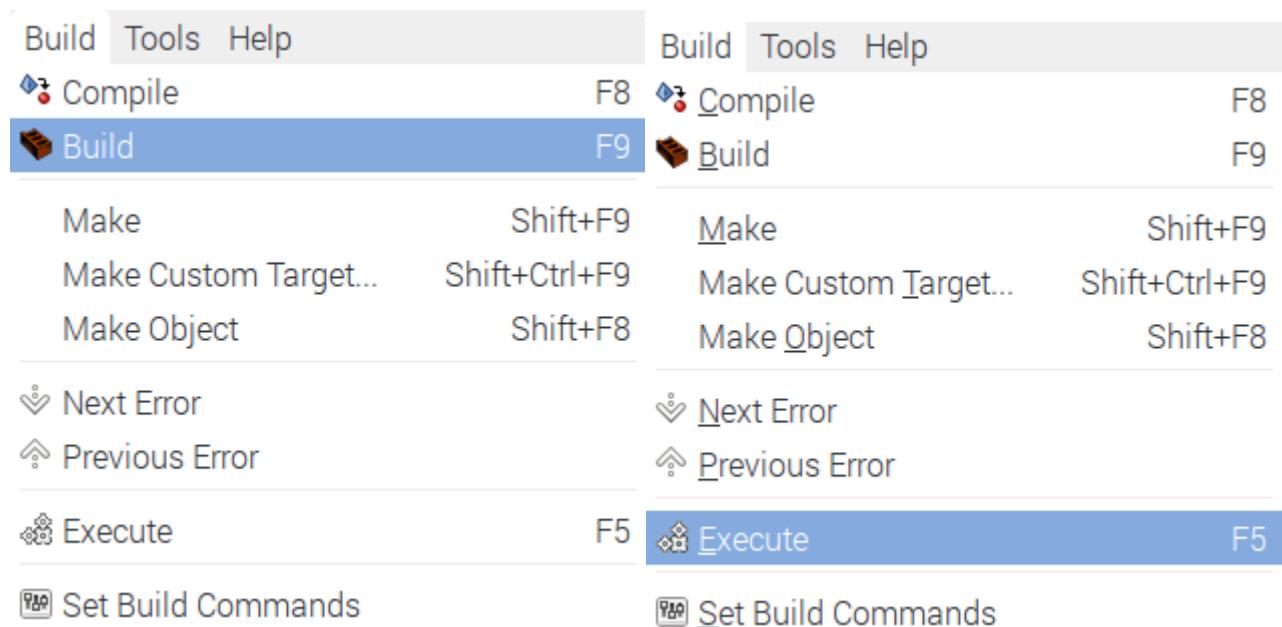

Or find and open Geany directly in the desktop main menu, and then click **File→Open** to open the "Hello.c", Or drag "Hello.c" to Geany directly.

If you want creat a new code, click **File→New→File→Save as** (name.c or name.py). Then write the code.

Generates an executable file by clicking menu bar Build->Build, then execute the generated file by clicking menu bar Build->Execute.

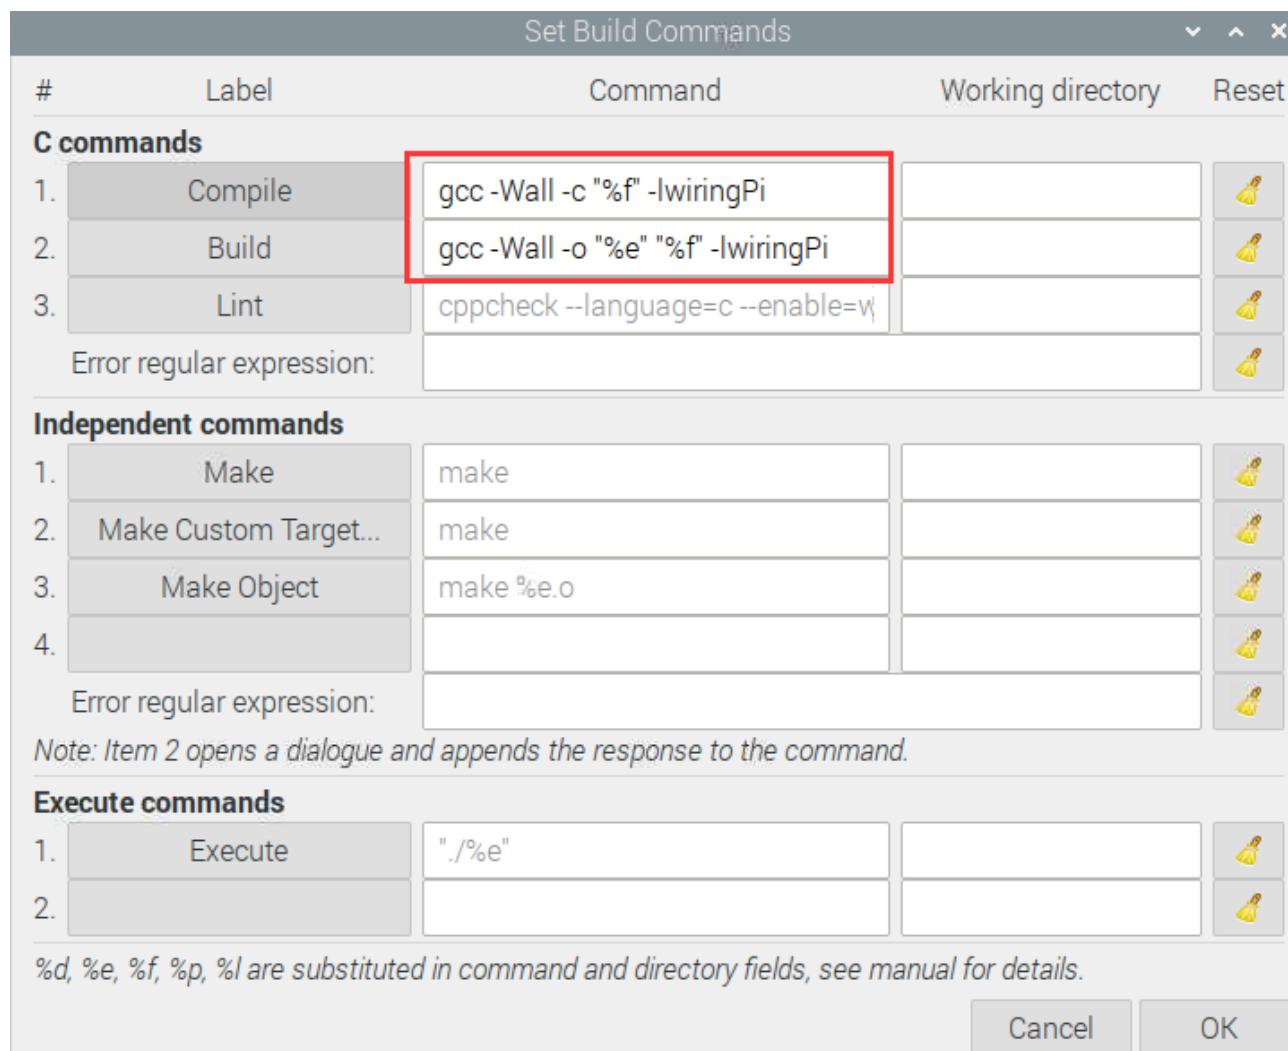

After the execution, there will be a terminal printing out the characters "Hello, World!", as shown below:

```
sh
File Edit Tabs Help
hello, world!

-----
(program exited with code: 1)
Press return to continue
```

A screenshot of a terminal window titled 'sh'. The window has a blue header bar with the title 'sh' and standard window control buttons (-, □, ×). The main area of the terminal shows the text 'hello, world!'. Below this, a dashed line separates the output from the exit message: '(program exited with code: 1)'. At the bottom of the terminal window, it says 'Press return to continue'.

You can click Build->Set Build Commands to set compiler commands. In later projects, we will use various compiler command options. If you choose to use Geany, you will need change the compiler command here. As is shown below:

## Summary

Here we have introduced three code editors. There also many other good code editors and you can choose any one you like.

In later projects, we will type commands in the terminal to execute code. We will explain the contents of the code in details. You can also use the editors to execute code. It is recommended to set default python3 first. Because most editors use python3 to execute the code.

## GPIO

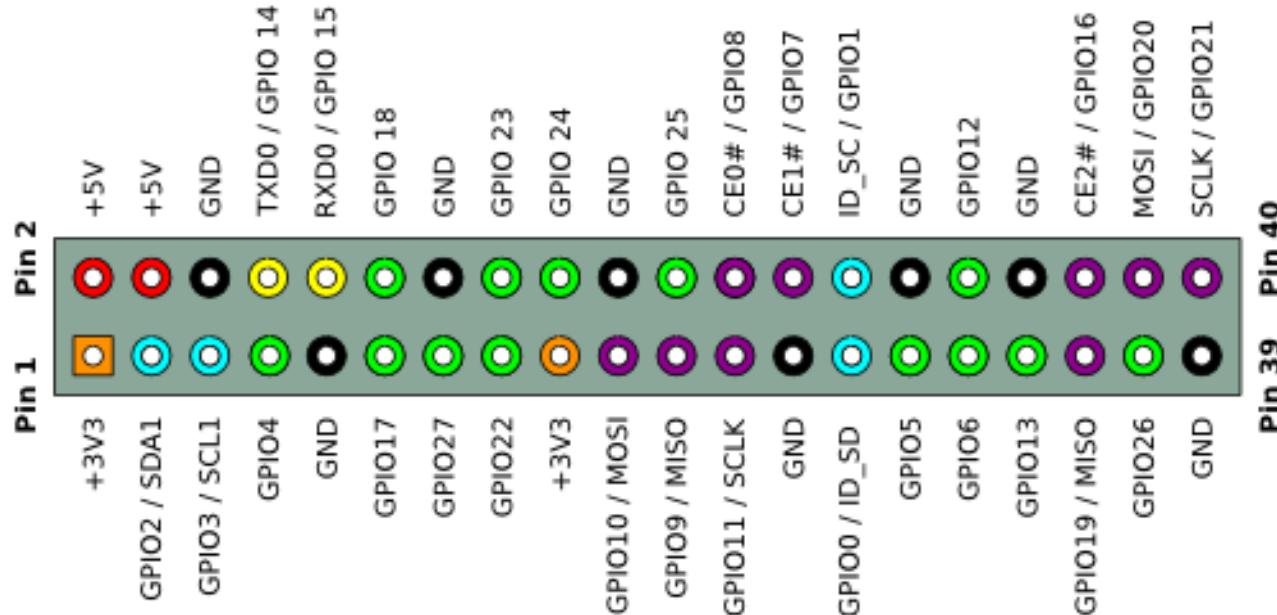

GPIO: General purpose input/output. We will introduce the specific feature of the pins on the Raspberry Pi and what you can do with them. You can use them for all sorts of purposes. Most of them can be used as either inputs or outputs, depending on your program.

When programming the GPIO pins there are 3 different ways to refer to them: GPIO numbering, physical numbering, WiringPi GPIO Numbering.

## BCM GPIO Numbering

Raspberry Pi CPU use BCM2835/BCM2836/BCM2837 of Broadcom. GPIO pin number is set by chip manufacturer. These are the GPIO pins as that computer recognizes. The numbers don't make any sense to humans. They jump all over the place, so there is no easy way to remember them. You will need a printed reference or a reference board that fits over the pins.

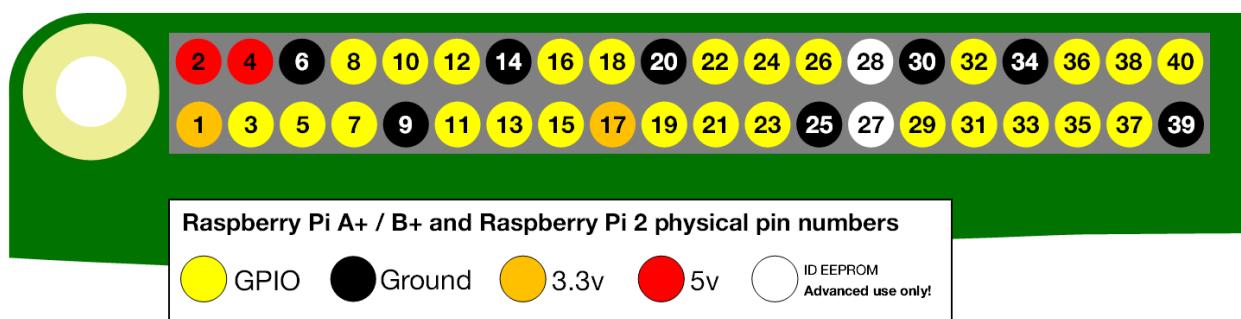

Each pin is defined as below:

For more details about pin definition of GPIO, please refer to <http://pinout.xyz/>

## PHYSICAL Numbering

Another way to refer to the pins is by simply counting across and down from pin 1 at the top left (nearest to the SD card). This is 'physical numbering', as shown below:

## WiringPi GPIO Numbering

Different from the previous mentioned two kinds of GPIO serial numbers, RPi GPIO serial number of the WiringPi was renumbered. Here we have three kinds of GPIO number mode: based on the number of BCM chip, based on the physical sequence number and based on wiringPi. The correspondence between these three GPIO numbers is shown below:

wiringPi Pin	BCM GPIO	Name	Header	Name	BCM GPIO	wiringPi Pin	
—	—	3.3v	1   2	5v	—	—	For A+, B+, 2B, 3B, 3B+, 4B, Zero
8	R1:0/R2:2	SDA	3   4	5v	—	—	
9	R1:1/R2:3	SCL	5   6	0v	—	—	
7	4	GPIO7	7   8	TxD	14	15	
—	—	0v	9   10	RxD	15	16	
0	17	GPIO0	11   12	GPIO1	18	1	
2	R1:21/R2:27	GPIO2	13   14	0v	—	—	
3	22	GPIO3	15   16	GPIO4	23	4	
—	—	3.3v	17   18	GPIO5	24	5	
12	10	MOSI	19   20	0v	—	—	
13	9	MISO	21   22	GPIO6	25	6	
14	11	SCLK	23   24	CE0	8	10	
—	—	0v	25   26	CE1	7	11	
30	0	SDA.0	27   28	SCL.0	1	31	
21	5	GPIO.21	29   30	0V	—	—	
22	6	GPIO.22	31   32	GPIO.26	12	26	
23	13	GPIO.23	33   34	0V	—	—	
24	19	GPIO.24	35   36	GPIO.27	16	27	
25	26	GPIO.25	37   38	GPIO.28	20	28	
		0V	39   40	GPIO.29	21	29	

wiringPi Pin	BCM GPIO	Name	Header	Name	BCM GPIO	wiringPi Pin	

(For more details, please refer to <https://projects.drogon.net/raspberry-pi/wiringpi/pins/> )

You can also use the following command to view their correspondence.

```
gpio readall
```

Pi 3 Model B

If you are using Raspberry Pi 4B, there will be errors when executing command “gpio readall”. As is below:

```
pi@raspberrypi:~ $ gpio readall
Oops - unable to determine board type... model: 17
```

This is because the official version of the library supporting 4B has not yet been released, which result in some commands can not be used properly. But it won't affect the next project. For this problem, you can solve it by installing a patch. Just execute the commands below in the terminal.

```
wget https://project-downloads.drogon.net/wiringpi-latest.deb
sudo dpkg -i wiringpi-latest.deb
```

After the installation is completed, Execute "gpio -v" and "gpio readall" commands again.

```
pi@raspberrypi:~ $ gpio -v

For more details about wiringPi, please refer to <http://wiringpi.com/>.

## GPIO Extension Board

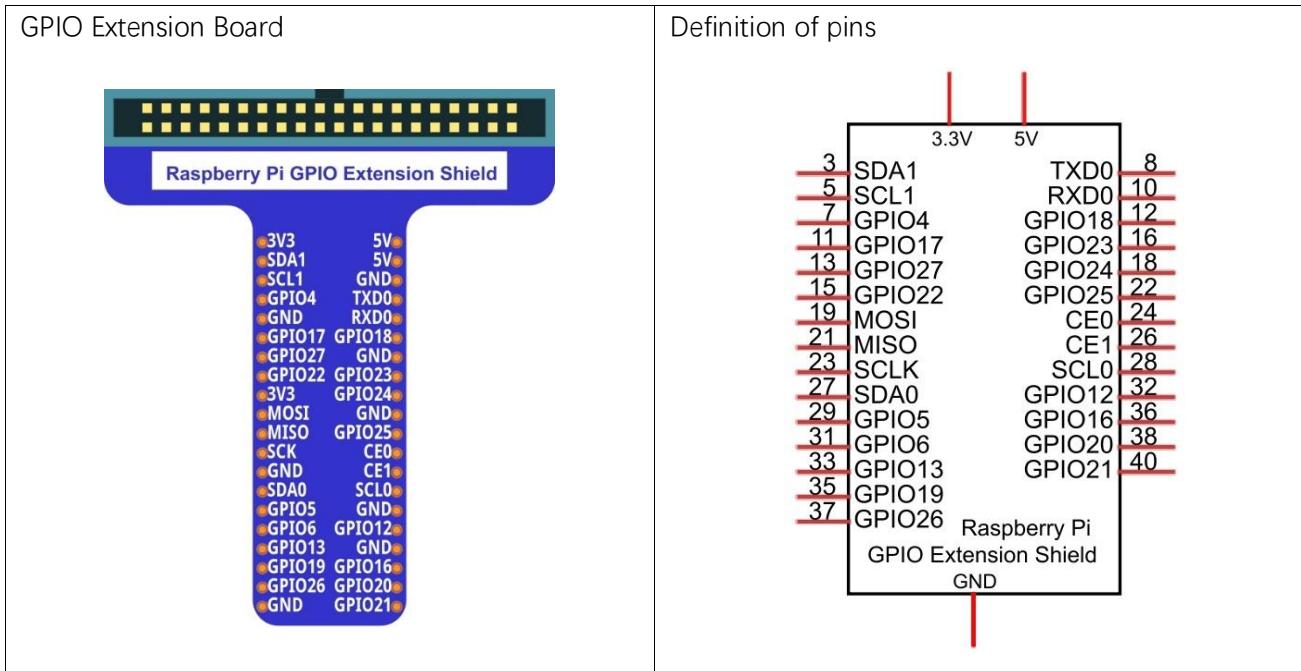

When we use RPi to do the project, we had better use GPIO, which is more convenient to extend all IO ports of RPi to the breadboard directly. The GPIO sequence on Extension Board is identical to the GPIO sequence of RPi. Since the GPIO of different versions of RPi is different, the corresponding extensions board are also different. For example, a GPIO extensions board with 40 pins is connected to RPi as follows:

Practicality picture of connection:

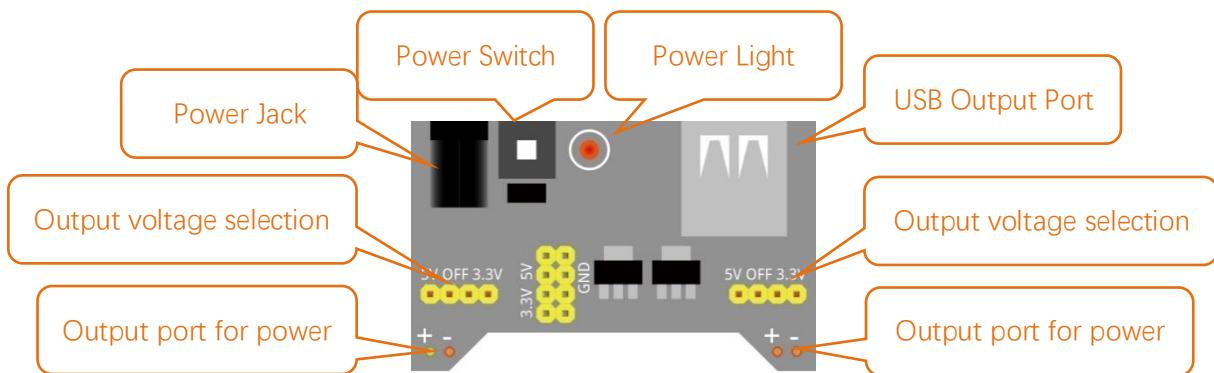

GPIO Extension Board and its schematic are shown below:

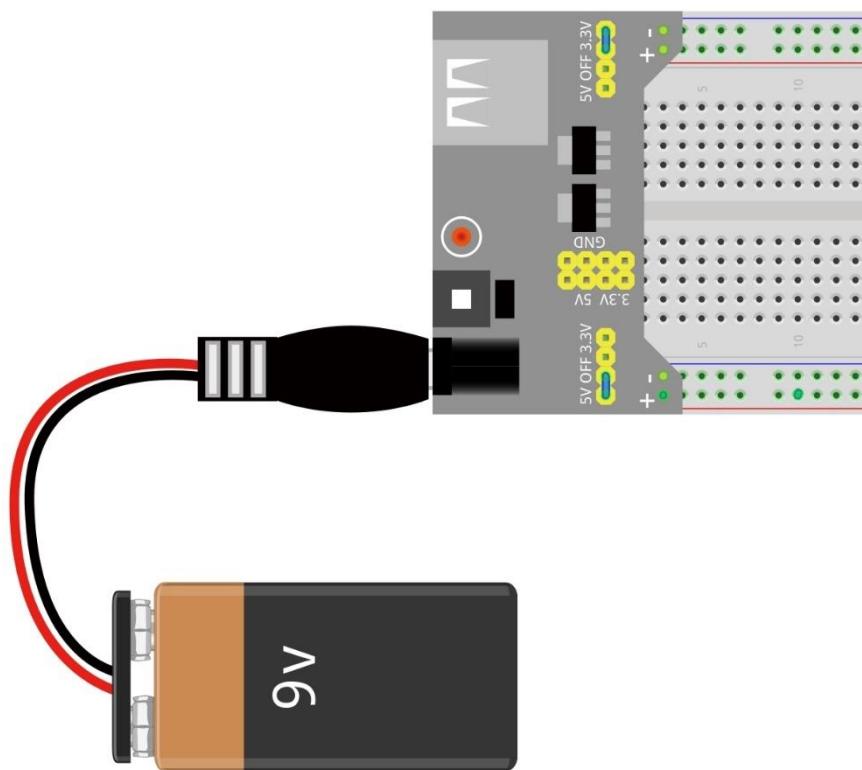

## Breadboard Power Module

Breadboard Power Module is an independent board, which can provide independent 5V or 3.3V power for bread board when used to build the circuit, and it can avoid excessive load power damaging RPi power. The schematic diagram of the Breadboard Power Module is shown below:

The connection between Breadboard Power Module and Breadboard is shown below:

## Next

Here, all preparations have been completed. Next, we will combine the RPi and electronic components to do a series of projects from easy to difficult and focus on explaining the relevant knowledge of electronic circuit.

# Chapter 1 LED

This chapter is the starting point of the journey to explore RPi electronic projects. Let's start with simple "Blink".

## Project 1.1 Blink

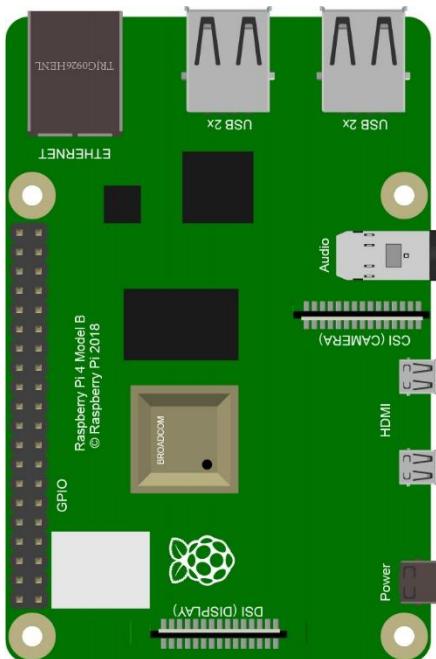

In this project, let's try to use RPi to control LED blinking.

### Component List

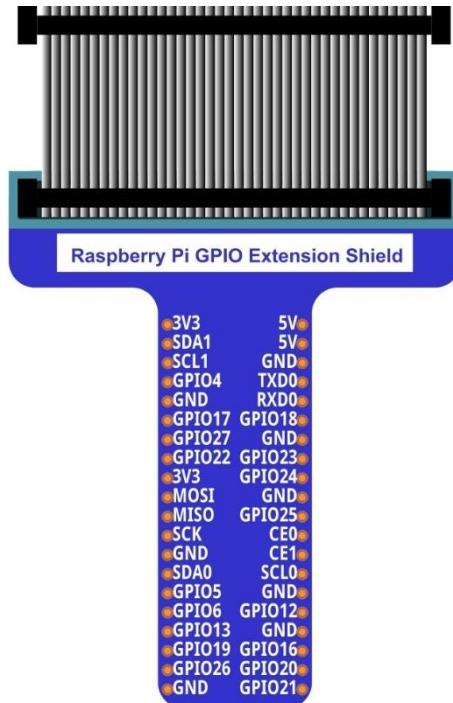

#### Raspberry Pi (

Recommended: Raspberry Pi 4B / 3B+ / 3B

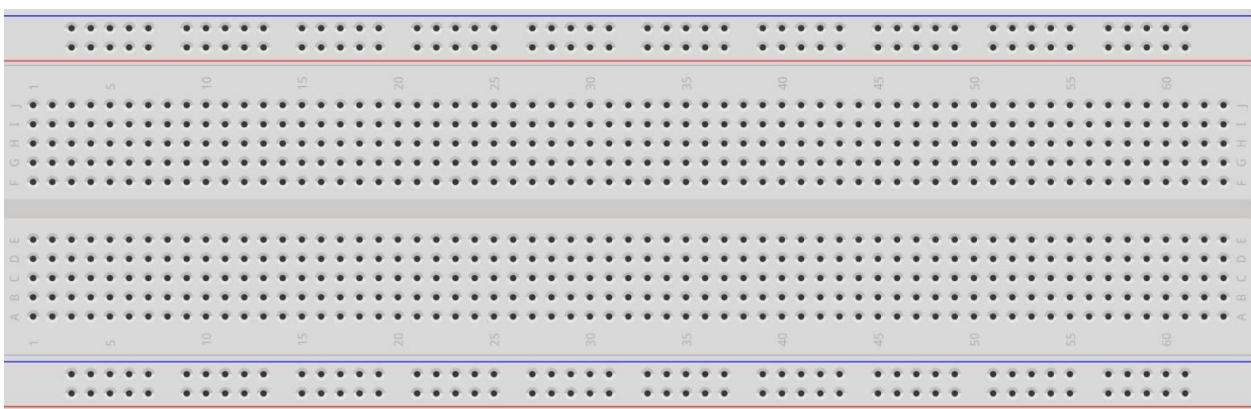

Compatible: 3A+ / 2B / 1B+ / 1A+ / Zero W / Zero)

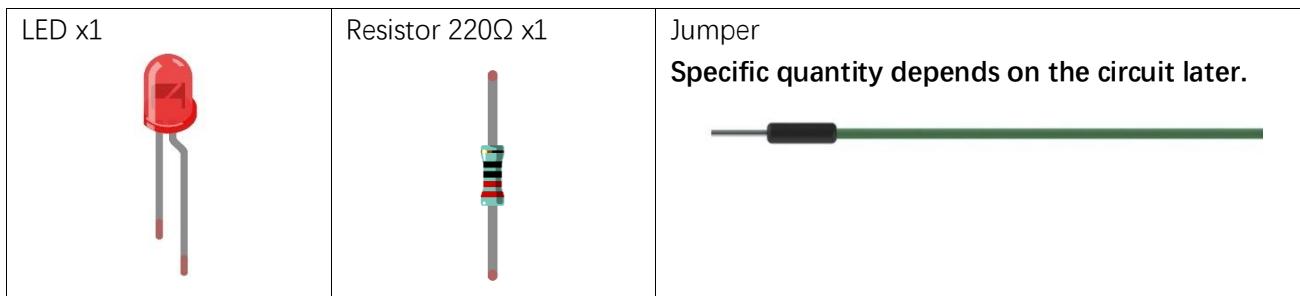

#### GPIO Extension Board & Wire x1

#### BreadBoard x1

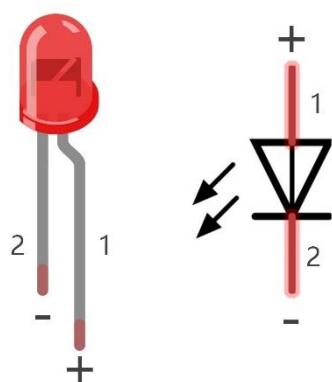

In the components list, 3B GPIO, Extension Shield Raspberry and Breadboard are necessary for each project. They will be listed only in text form later.

## Component knowledge

### LED

LED is a kind of diode. LED will shine only if the long pin of LED is connected to the positive electrode and the short pin is connected to negative electrode.

This is also the features of the common diode. Diode works only if the voltage of its positive electrode is higher than its negative electrode.

LED	Voltage	Maximum current	Recommended current
Red	1.9-2.2V	20mA	10mA
Green	2.9-3.4V	10mA	5mA
Blue	2.9-3.4V	10mA	5mA

Volt ampere characteristics conform to diode

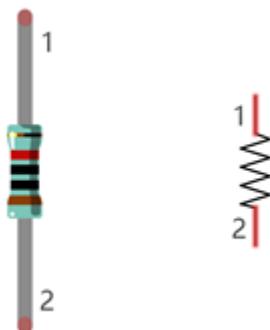

The LED can not be directly connected to power supply, which can damage component. A resistor with certain resistance must be connected in series in the circuit of LED.

### Resistor

The unit of resistance(R) is ohm(Ω).  $1M\Omega=1000k\Omega$ ,  $1k\Omega=1000\Omega$ .

Resistor is an electrical component that limits or regulates the flow of current in an electronic circuit.

The left is the appearance of resistor, and the right is the symbol of resistor represented in circuit.

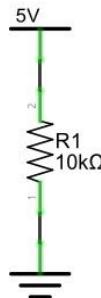

Color rings attached to the resistor is used to indicate its resistance. For more details of resistor color code, please refer to the resistor card in the package.

With the same voltage there will be less current with more resistance. And the links among current, voltage and resistance can be expressed by the formula below:  $I=U/R$ .

In the following diagram, the current through R1 is:  $I=U/R=5V/10k\Omega=0.0005A=0.5mA$ .

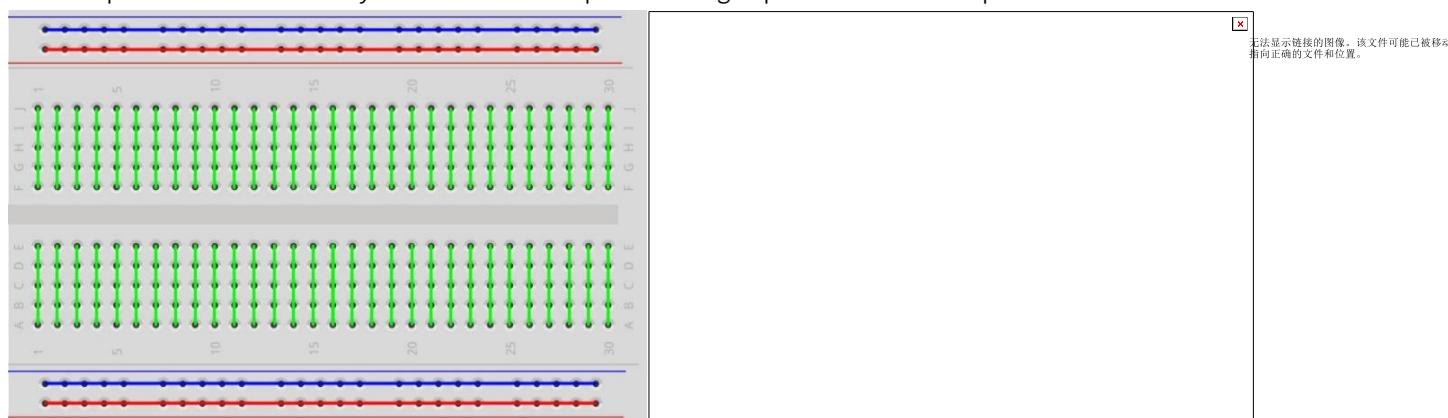

Do not connect the two poles of power supply with low resistance, which will make the current too high to damage power supply. And resistor has no poles.

### Breadboard

Take a short breadboard as an example to introduce its feature, as below.

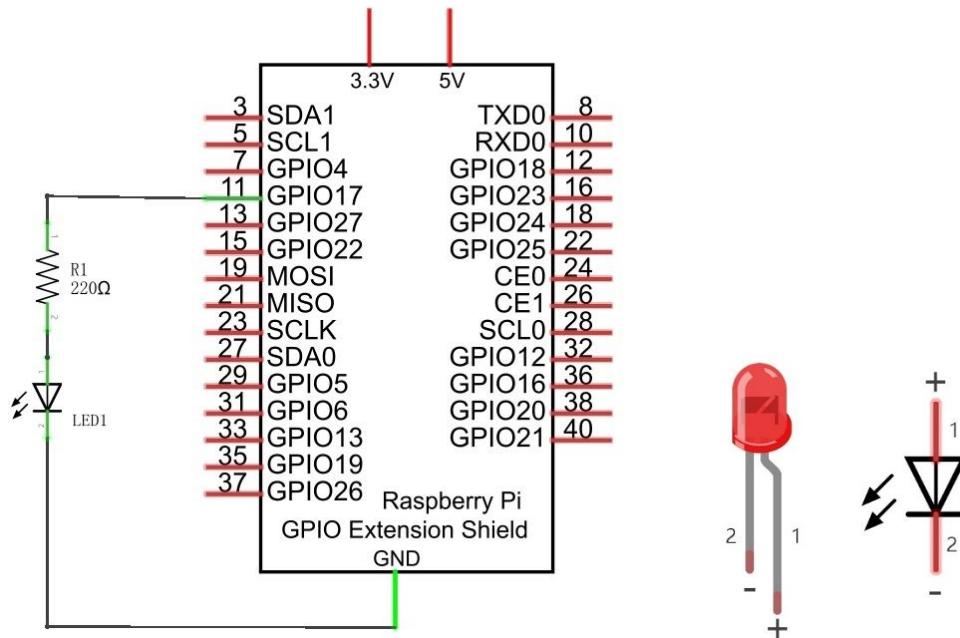

The left picture shows the way of connection of pins. The right picture shows the practical internal structure.

## Circuit

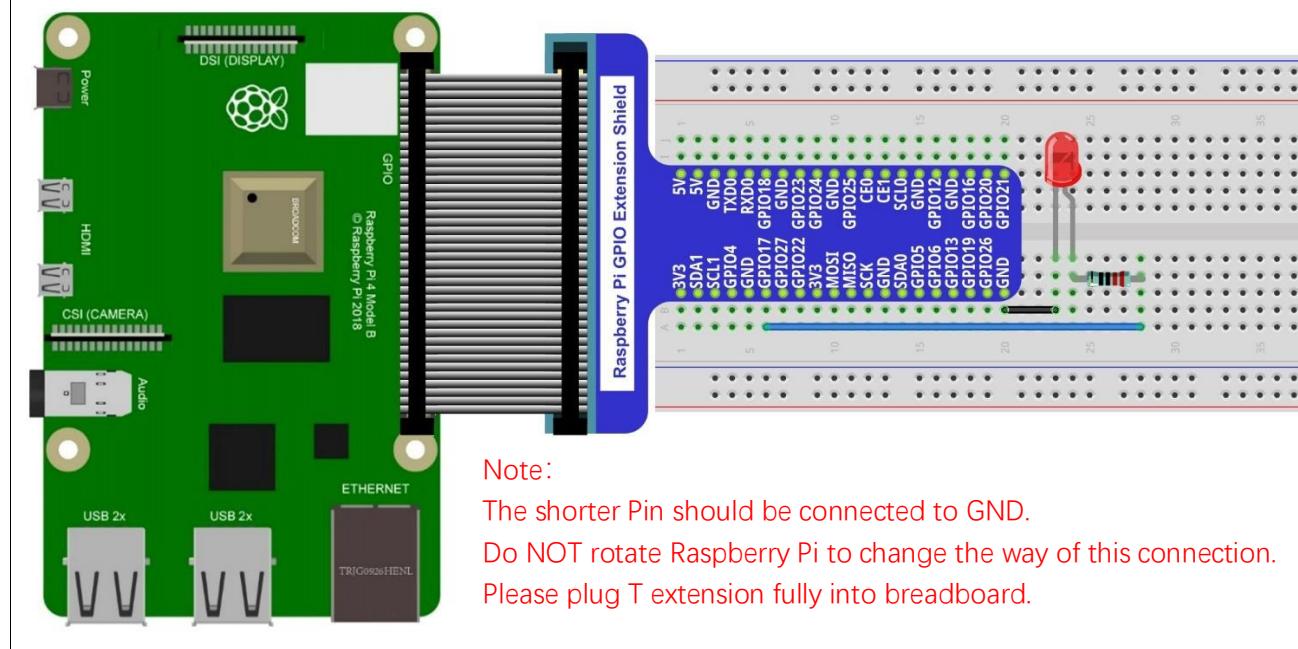

Disconnect RPi from GPIO Extension Shield first. Then build the circuit according to the circuit diagram and the hardware connection diagram. After the circuit is built and confirmed, connect RPi to GPIO Extension Shield. In addition, short circuit (especially 5V and GND, 3.3V and GND) should be avoid, because short circuit may cause abnormal circuit work, or even damage to RPi.

Schematic diagram

Hardware connection.

If you need any support, please contact us via: [support@freenove.com](mailto:support@freenove.com)

Because Numbering of GPIO Extension Shield is the same as RPi GPIO, later Hardware connection diagram will only show the part of breadboard and GPIO Extension Shield.

## Code

According to the circuit, when the GPIO17 of RPi output high level, LED is turned on. Conversely, when the GPIO17 RPi output low level, LED is turned off. Therefore, we can let GPIO17 output high and low level in cycle to make LED blink. We will use both C code and Python code to achieve the goal.

### C Code 1.1.1 Blink

First, execute command into the terminal one by one. Then observe the project result, and view the code.

If you have any concerns, please contact us via: [support@freenove.com](mailto:support@freenove.com)

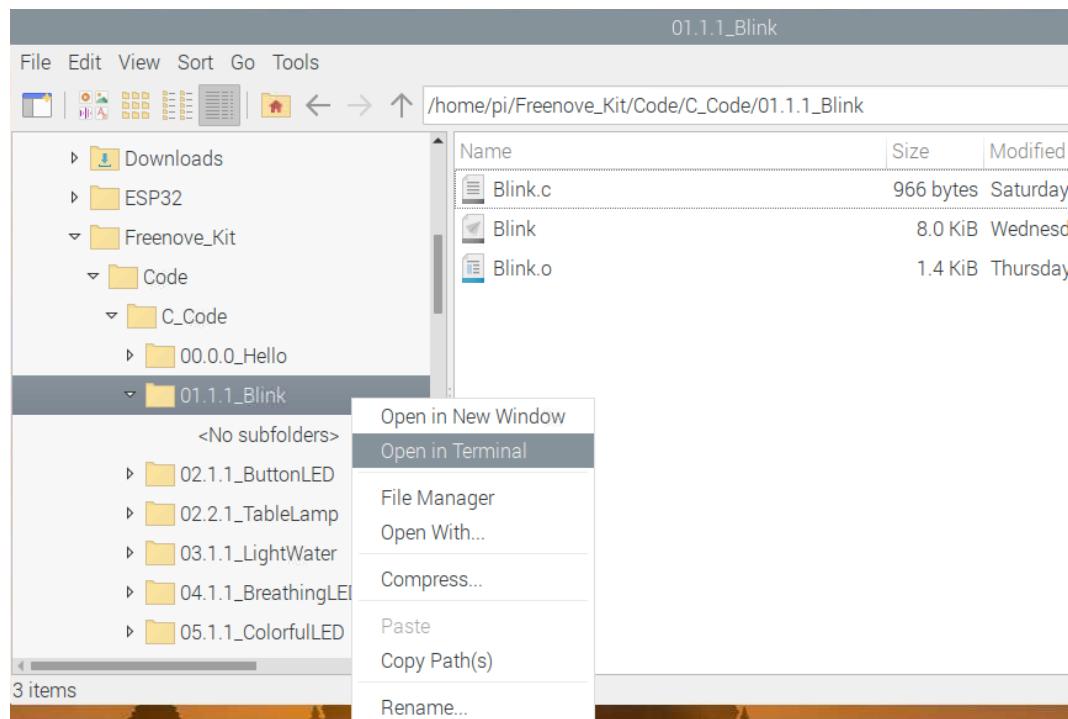

If you want to execute it with Geany, please refer to section [Code Editor](#) to configure.

It is recommended to execute code as below.

1. Use cd command to enter 01.1.1\_Blink directory of C code.

```
cd ~/Freenove_Kit/Code/C_Code/01.1.1_Blink
```

You can also use the file browser. In the folder tree on the left, right-click the folder you want to enter, and click "Open in Terminal".

2. Use the following command to compile the code "Blink.c" and generate executable file "Blink".

**"I" of "lwiringPi" is low case of "L".**

```
gcc Blink.c -o Blink -lwiringPi
```

3. Then run the generated file "blink".

```
sudo ./Blink
```

Now, LED start blink.

If C code doesn't work, please execute command below and try again with C code.

```
wget https://project-downloads.drogon.net/wiringpi-latest.deb
sudo dpkg -i wiringpi-latest.deb
```

```
pi@raspberrypi:~/Freenove_Kit/Code/C_Code/01.1.1_Blink
pi@raspberrypi:~/Freenove_Kit/Code/C_Code/01.1.1_Blink$ gcc Blink.c -o Blink -lwiringPi
pi@raspberrypi:~/Freenove_Kit/Code/C_Code/01.1.1_Blink$ sudo ./Blink
Program is starting ...
Using pin0
led turned on >>>
led turned off <<<
```

You can press "Ctrl+C" to end the program. The following is the program code:

```
1 #include <wiringPi.h>
2 #include <stdio.h>
3
4 #define ledPin 0 //define the led pin number
5
6 void main(void)
7 {
8     printf("Program is starting ... \n");
9
10    wiringPiSetup(); //Initialize wiringPi.
11
12    pinMode(ledPin, OUTPUT); //Set the pin mode
13    printf("Using pin%d\n", ledPin); //Output information on terminal
14    while(1) {
15        digitalWrite(ledPin, HIGH); //Make GPIO output HIGH level
16        printf("led turned on >>>\n"); //Output information on terminal
17        delay(1000); //Wait for 1 second
18        digitalWrite(ledPin, LOW); //Make GPIO output LOW level
19        printf("led turned off <<<\n"); //Output information on terminal
20        delay(1000); //Wait for 1 second
21    }
22 }
```

GPIO connected to ledPin in the circuit is GPIO17. And GPIO17 is defined as 0 in the wiringPi numbering. So ledPin should be defined as 0 pin. You can refer to the corresponding table in Chapter 0.

```
#define ledPin 0 //define the led pin number
```

In the main function main(), initialize wiringPi first.

```
wiringPiSetup(); //Initialize wiringPi.
```

After the wiringPi is initialized successfully, set the ledPin to output mode. And then enter the while loop, which is endless. That is, the program will always be executed in this loop, unless it is ended by operation from loop outside. In this cycle, use digitalWrite (ledPin, HIGH) to make ledPin output high level, then LED is turned on. After a period of time delay, use digitalWrite(ledPin, LOW) to make ledPin output low level, then LED is turned off, which is followed by a delay. Repeat the cycle, then LED will start blinking.

```
pinMode(ledPin, OUTPUT); //Set the pin mode
printf("Using pin%d\n", %ledPin); //Output information on terminal
while(1) {
    digitalWrite(ledPin, HIGH); //Make GPIO output HIGH level
    printf("led turned on >>>\n"); //Output information on terminal
    delay(1000); //Wait for 1 second
    digitalWrite(ledPin, LOW); //Make GPIO output LOW level
    printf("led turned off <<<\n"); //Output information on terminal
    delay(1000); //Wait for 1 second
}
```

Among code above, there are two important functions as below:

**void pinMode(int pin, int mode);**

This sets the mode of a pin to either INPUT, OUTPUT, PWM\_OUTPUT or GPIO\_CLOCK. Note that only wiringPi pin 1 (BCM\_GPIO 18) supports PWM output and only wiringPi pin 7 (BCM\_GPIO 4) supports CLOCK output modes.

This function has no effect when in Sys mode. If you need to change the pin mode, then you can do it with the gpio program in a script before you start your program

**void digitalWrite (int pin, int value);**

Writes the value HIGH or LOW (1 or 0) to the given pin which must have been previously set as an output.

For more related functions of wiringPi, please refer to <http://wiringpi.com/reference/>

### Python Code 1.1.1 Blink

Net, we will use Python language to make LED blink.

First, observe the project result, and then view the code.

If you have any concerns, please contact us via: support@freenove.com

1. Use cd command to enter 01.1.1\_Blink directory of Python code.

```
cd ~/Freenove_Kit/Code/Python_Code/01.1.1_Blink
```

2. Use python command to execute python code blink.py.

```
python Blink.py
```

Now, LED start blinking.

```
pi@raspberrypi:~ $ cd Freenove_Kit/Code/Python_Code/01.1.1_Blink/
pi@raspberrypi:~/Freenove_Kit/Code/Python_Code/01.1.1_Blink $ python Blink.py
Program is starting ...

using pin11
led turned on >>>
led turned off <<<
```

You can press “Ctrl+C” to end the program. The following is the program code:

```

1 import RPi.GPIO as GPIO
2 import time
3
4 ledPin = 11      # define ledPin
5
6 def setup():
7     GPIO.setmode(GPIO.BOARD)      # use PHYSICAL GPIO Numbering
8     GPIO.setup(ledPin, GPIO.OUT)   # set the ledPin to OUTPUT mode
9     GPIO.output(ledPin, GPIO.LOW)  # make ledPin output LOW level
10    print ('using pin%d'%ledPin)
11
12 def loop():
13     while True:
14         GPIO.output(ledPin, GPIO.HIGH) # make ledPin output HIGH level to turn on led
15         print ('led turned on >>>')      # print information on terminal
16         time.sleep(1)                  # Wait for 1 second
17         GPIO.output(ledPin, GPIO.LOW)   # make ledPin output LOW level to turn off led
18         print ('led turned off <<<')
19         time.sleep(1)                  # Wait for 1 second
20
21 def destroy():
22     GPIO.cleanup()                  # Release all GPIO
23
24 if __name__ == '__main__':      # Program entrance
```

```

25     print ('Program is starting ... \n')
26     setup()
27     try:
28         loop()
29     except KeyboardInterrupt: # Press ctrl-c to end the program.
30         destroy()

```

In subfunction `setup()`, `GPIO.setmode(GPIO.BOARD)` is used to set the serial number for GPIO based on physical location of the pin. `GPIO17` use pin 11 of the board, so define `ledPin` as 11 and set `ledPin` to output mode (output low level).

```

ledPin = 11      # define ledPin

def setup():
    GPIO.setmode(GPIO.BOARD)      # use PHYSICAL GPIO Numbering
    GPIO.setup(ledPin, GPIO.OUT)   # set the ledPin to OUTPUT mode
    GPIO.output(ledPin, GPIO.LOW)  # make ledPin output LOW level
    print ('using pin%d' %ledPin)

```

In `loop()`, there is an endless while loop. That is, the program will always be executed unless it is ended by operation outside the loop, like “`Ctrl+C`”. In this loop, set `ledPin` output high level, then LED is turned on. After a period of time delay, set `ledPin` output low level, then LED is turned off, which is followed by a delay. Repeat the loop, then LED will start blinking.

```

def loop():
    while True:
        GPIO.output(ledPin, GPIO.HIGH)  # make ledPin output HIGH level to turn on led
        print ('led turned on >>>')  # print information on terminal
        time.sleep(1)                  # Wait for 1 second
        GPIO.output(ledPin, GPIO.LOW)   # make ledPin output LOW level to turn off led
        print ('led turned off <<<')
        time.sleep(1)                  # Wait for 1 second

```

Finally, when the program is terminated, subfunction will be executed, the LED will be turned off and then the IO port will be released. If close the program terminal directly, the program will be terminated too, but `finish()` function will not be executed. So, GPIO resources won't be released, in the warning message may appear next time you use GPIO. So, it is not a good habit to close the program terminal directly.

```

def finish():
    GPIO.cleanup()                  # Release all GPIO

```

About RPi.GPIO:

**RPi.GPIO**

This is a Python module to control the GPIO on a Raspberry Pi. It includes basic output function and input function of GPIO, and function used to generate PWM.

**GPIO.setmode(mode)**

Set the mode for pin serial number of GPIO.

mode=GPIO.BOARD, which represents the GPIO pin serial number is based on physical location of RPi.

mode=GPIO.BCM, which represents the pin serial number is based on CPU of BCM chip.

**GPIO.setup(pin, mode)**

Set pin to input mode or output mode. "pin" for the GPIO pin, "mode" for INPUT or OUTPUT.

**GPIO.output(pin, mode)**

Set pin to output mode. "pin" for the GPIO pin, "mode" for HIGH (high level) or LOW (low level).

For more functions related to RPi.GPIO, please refer to:

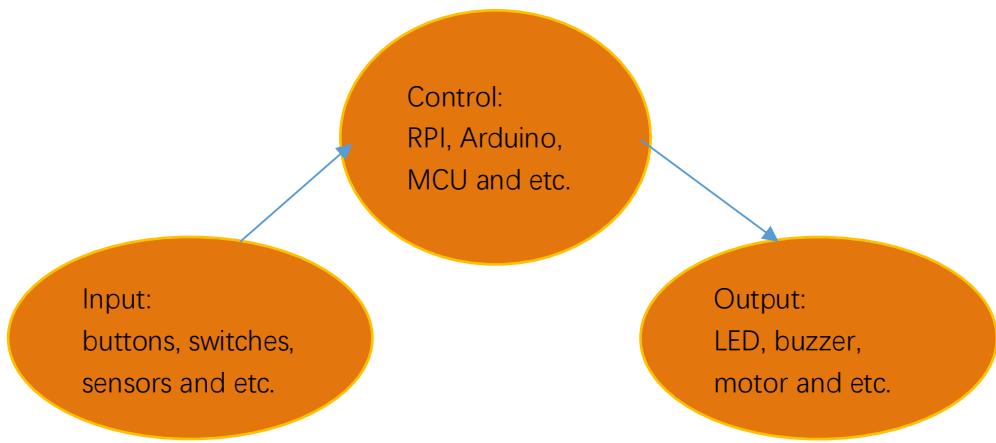

<https://sourceforge.net/p/raspberry-gpio-python/wiki/Examples/>

"import time" time is a module of python.

<https://docs.python.org/2/library/time.html?highlight=time%20time#module-time>

# Chapter 2 Button & LED

Usually, there are three essential parts in a complete automatic control device: INPUT, OUTPUT, and CONTROL. In last section, the LED module is the output part and RPI is the control part. In practical applications, we not only just let the LED lights flash, but make the device sense the surrounding environment, receive instructions and then make the appropriate action such as lights the LED, make a buzzer beep and so on.

Next, we will build a simple control system to control LED through a button.

## Project 2.1 Button & LED

In the project, we will control the LED state through a button. When the button is pressed, LED will be turn on, and when it is released, LED will be turn off.

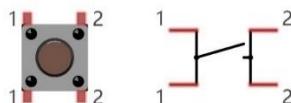

### Component List

Raspberry Pi (with 40 GPIO) x1 GPIO Extension Board & Wire x1 BreadBoard x1	LED x1 	Resistor 220Ω x1 	Resistor 10kΩ x2 	Push button x1 
Jumper 				

## Component knowledge

### Push button

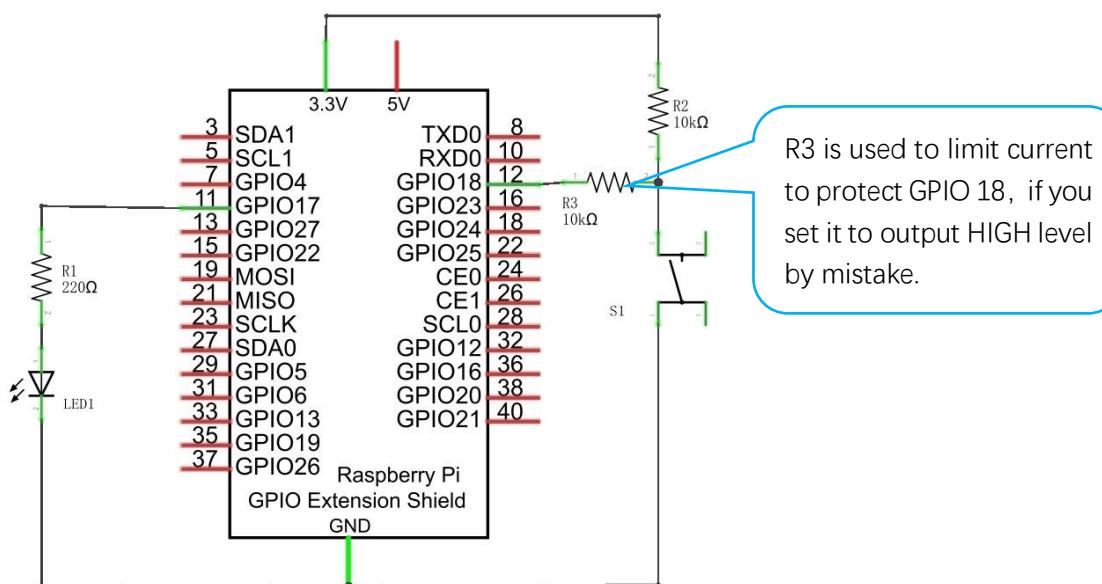

Push button has 4 pins. Two pins on the left is connected, and the right is similar as the left, which is shown in the below:

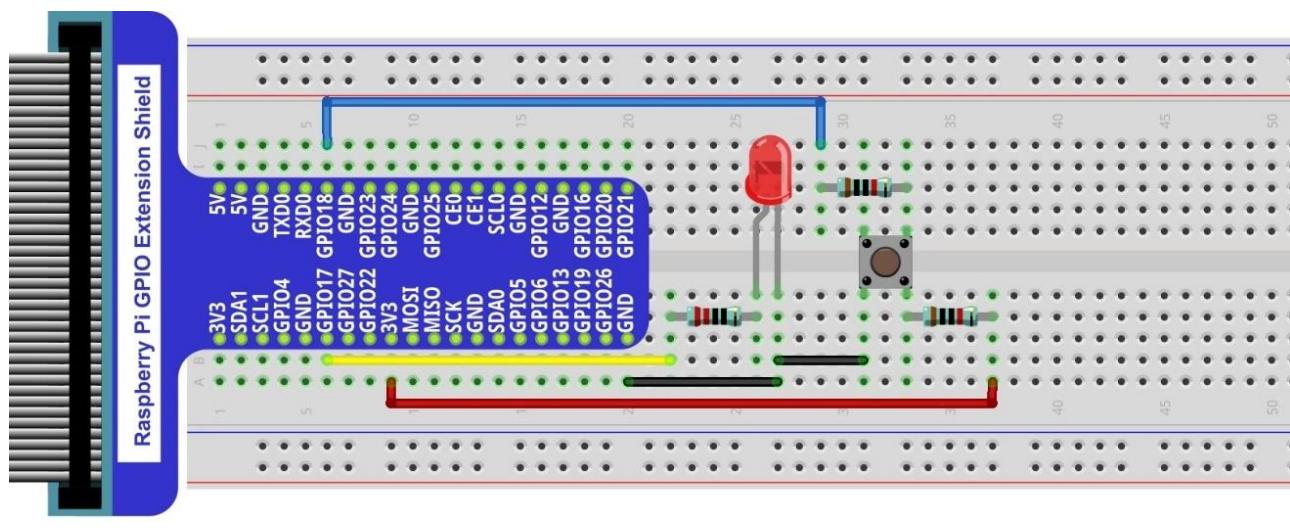

When the push button is pressed, the circuit is turned on.

## Circuit

Schematic diagram

Hardware connection. If you need any support, please feel free to contact us via: [support@freenove.com](mailto:support@freenove.com)

## Code

This project is designed for learning how to use button to control LED. We first need to read the state of button, and then determine whether turn on LED according to the state of the button.

### C Code 2.1.1 ButtonLED

First, observe the project result, then view the code.

**If you have any concerns, please contact us via: support@freenove.com**

1. Use cd command to enter 02.1.1\_ButtonLED directory of C code.

```
cd ~/Freenove_Kit/Code/C_Code/02.1.1_ButtonLED
```

2. Use the following command to compile the code "ButtonLED.c" and generate executable file "ButtonLED"

```
gcc ButtonLED.c -o ButtonLED -lwiringPi
```

3. Then run the generated file "ButtonLED".

```
sudo ./ButtonLED
```

Later, the terminal window continues to print out the characters "led off...". Press the button, then LED is turned on and then terminal window prints out the "led on...". Release the button, then LED is turned off and then terminal window prints out the "led off...". You can press "Ctrl+C" to terminate the program.

The following is the program code:

```

1 #include <wiringPi.h>
2 #include <stdio.h>
3
4 #define ledPin    0 //define the ledPin
5 #define buttonPin 1 //define the buttonPin
6
7 void main(void)
8 {
9     printf("Program is starting ... \n");
10
11     wiringPiSetup(); //Initialize wiringPi.
12
13     pinMode(ledPin, OUTPUT); //Set ledPin to output
14     pinMode(buttonPin, INPUT); //Set buttonPin to input
15
16     pullUpDnControl(buttonPin, PUD_UP); //pull up to HIGH level
17     while(1) {
18         if(digitalRead(buttonPin) == LOW){ //button is pressed
19             digitalWrite(ledPin, HIGH); //Make GPIO output HIGH level
20             printf("Button is pressed, led turned on >>\n"); //Output information on
21             terminal
22         }
23         else { //button is released
24             digitalWrite(ledPin, LOW); //Make GPIO output LOW level
25             printf("Button is released, led turned off <<\n"); //Output information on
26             terminal

```

```
27 }  
28 }  
29 }
```

In the circuit connection, LED and Button are connected with GPIO17 and GPIO18 respectively, which correspond to 0 and 1 respectively in wiringPi. So define ledPin and buttonPin as 0 and 1 respectively.

```
#define ledPin 0 //define the ledPin  
#define buttonPin 1 //define the buttonPin
```

In the while loop of main function, use digitalWrite(buttonPin) to determine the state of Button. When the button is pressed, the function returns low level, the result of "if" is true, and then turn on LED. Or, turn off LED.

```
if(digitalRead(buttonPin) == LOW) { //button has pressed down  
    digitalWrite(ledPin, HIGH); //led on  
    printf("led on... \n");  
}  
else { //button has released  
    digitalWrite(ledPin, LOW); //led off  
    printf("... led off\n");  
}
```

Reference:

```
int digitalRead (int pin);
```

This function returns the value read at the given pin. It will be "**HIGH**" or "**LOW**"(1 or 0) depending on the logic level at the pin.

### Python Code 2.1.1 ButtonLED

First, observe the project result, then view the code.

If you have any concerns, please contact us via: support@freenove.com

1. Use cd command to enter 02.1.1\_ButtonLED directory of Python code.

**cd ~/Freenove\_Kit/Code/Python\_Code/02.1.1\_ButtonLED**

2. Use Python command to execute btnLED.py.

**python ButtonLED.py**

Later, the terminal window continue to print out the characters "led off...", press the button, then LED is turned on and then terminal window print out the "led on...". Release the button, then LED is turned off and then terminal window print out the "led off...". You can press "Ctrl+C" to terminate the program.

The following is the program code:

```
1 import RPi.GPIO as GPIO
2
3 ledPin = 11      # define ledPin
4 buttonPin = 12    # define buttonPin
5
6 def setup():
7
8     GPIO.setmode(GPIO.BOARD)      # use PHYSICAL GPIO Numbering
9     GPIO.setup(ledPin, GPIO.OUT)   # set ledPin to OUTPUT mode
10    GPIO.setup(buttonPin, GPIO.IN, pull_up_down=GPIO.PUD_UP)    # set buttonPin to PULL UP
11    INPUT mode
12
13 def loop():
14     while True:
15         if GPIO.input(buttonPin)==GPIO.LOW: # if button is pressed
16             GPIO.output(ledPin,GPIO.HIGH)    # turn on led
17             print (' led turned on >>>')  # print information on terminal
18         else : # if button is released
19             GPIO.output(ledPin,GPIO.LOW) # turn off led
20             print (' led turned off <<<')
21
22 def destroy():
23     GPIO.cleanup()                  # Release GPIO resource
24
25 if __name__ == '__main__':      # Program entrance
26     print ('Program is starting...')
27     setup()
28     try:
29         loop()
30     except KeyboardInterrupt: # Press ctrl-c to end the program.
31         destroy()
```

In subfunction setup (), GPIO.setmode (GPIO.BOARD) is used to set the serial number of the GPIO, which is based on physical location of the pin. So, GPIO17 and GPIO18 correspond to pin11 and pin12 respectively in the circuit. Then set ledPin to output mode, buttonPin to input mode with a pull resistor.

```
ledPin = 11      # define ledPin
buttonPin = 12    # define buttonPin

def setup():
    GPIO.setmode(GPIO.BOARD)      # use PHYSICAL GPIO Numbering
    GPIO.setup(ledPin, GPIO.OUT)   # set ledPin to OUTPUT mode
    GPIO.setup(buttonPin, GPIO.IN, pull_up_down=GPIO.PUD_UP)  # set buttonPin to PULL UP
    INPUT mode
```

In the loop function, the endless loop while continue judging whether the key is pressed. When the button is pressed, the GPIO.input(buttonPin) will return low level, then the result of "if" is true, ledPin outputs high level, LED is turned on. Or, LED will be turned off.

```
def loop():
    while True:
        if GPIO.input(buttonPin)==GPIO.LOW: # if button is pressed
            GPIO.output(ledPin,GPIO.HIGH)  # turn on led
            print ('led turned on >>>')  # print information on terminal
        else : # if button is released
            GPIO.output(ledPin,GPIO.LOW) # turn off led
            print ('led turned off <<<')
```

Execute the function destroy (), which will close the program and release the RPI GPIO resource.

About function GPIO.input ():

### GPIO. input ()

This function returns the value read at the given pin. It will be “**HIGH**” or “**LOW**”(1 or 0) depending on the logic level at the pin.

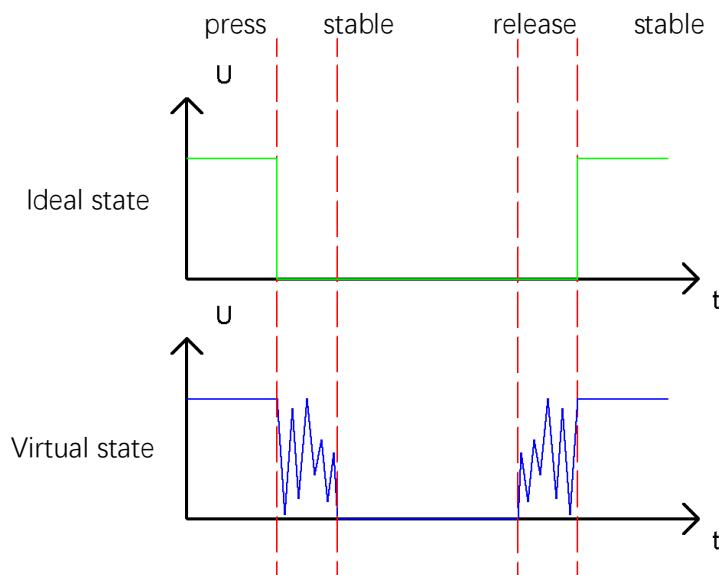

## Project 2.2 MINI table lamp

We will also use a button, LED and RPi to make a MINI table lamp. But the function is different: Press the button, the LED will be turned on, and press the button again, the LED goes out.

First, let us learn some knowledge about the button.

### Debounce for Push Button

When a Push Button is pressed, it will not change from one state to another state immediately. Due to mechanical vibration, there will be a continuous buffering before it becomes another state. And the releasing situation is similar with that process.

Therefore, if we directly detect the state of Push Button, there may be multiple pressing and releasing action in one pressing process. The buffering will mislead the high-speed operation of the microcontroller to cause a lot of false judgments. So we need to eliminate the impact of buffering. Our solution is: to judge the state of the button several times. Only when the button state is stable after a period of time, can it indicate that the button is pressed down.

This project needs the same components and circuits with the last section.

## Code

In the project, we still detect the state of Button to control LED. Here we need to define a variable to save the state of LED. And when the button is pressed once, the state of LED will be changed once. This has achieved the function of the table lamp.

### C Code 2.2.1 Tablelamp

First observe the project result, and then view the code.

If you have any concerns, please contact us via: support@freenove.com

1. Use cd command to enter 02.2.1\_Tablelamp directory of C code.

```
cd ~/Freenove_Kit/Code/C_Code/02.2.1_Tablelamp
```

2. Use following command to compile "Tablelamp.c" and generate executable file "Tablelamp".

```
gcc Tablelamp.c -o Tablelamp -lwiringPi
```

3. Tablelamp. Then run the generated file "Tablelamp".

```
sudo ./Tablelamp
```

When the program is executed, press the Button once, then LED is turned on. Press the Button another time, then LED is turned off.

```
1 #include <wiringPi.h>
2 #include <stdio.h>
3
4 #define ledPin    0 //define the ledPin
5 #define buttonPin 1 //define the buttonPin
6 int ledState=LOW; //store the State of led
7 int buttonState=HIGH; //store the State of button
8 int lastbuttonState=HIGH; //store the lastState of button
9 long lastChangeTime; //store the change time of button state
10 long captureTime=50; //set the stable time for button state
11 int reading;
12 int main(void)
13 {
14     printf("Program is starting...\n");
15
16     wiringPiSetup(); //Initialize wiringPi.
17
18     pinMode(ledPin, OUTPUT); //Set ledPin to output
19     pinMode(buttonPin, INPUT); //Set buttonPin to input
20
21     pullUpDnControl(buttonPin, PUD_UP); //pull up to high level
22     while(1) {
23         reading = digitalRead(buttonPin); //read the current state of button
24         if( reading != lastbuttonState){ //if the button state has changed, record the time
25             point
26             lastChangeTime = millis();
27         }
28     }
29 }
```

```

28     //if changing-state of the button last beyond the time we set, we consider that
29     //the current button state is an effective change rather than a buffeting
30     if(millis() - lastChangeTime > captureTime){
31         //if button state is changed, update the data.
32         if(reading != buttonState){
33             buttonState = reading;
34             //if the state is low, it means the action is pressing
35             if(buttonState == LOW){
36                 printf("Button is pressed!\n");
37                 ledState = !ledState; //Reverse the LED state
38                 if(ledState){
39                     printf("turn on LED ... \n");
40                 }
41                 else {
42                     printf("turn off LED ... \n");
43                 }
44             }
45             //if the state is high, it means the action is releasing
46             else {
47                 printf("Button is released!\n");
48             }
49         }
50     }
51     digitalWrite(ledPin, ledState);
52     lastbuttonState = reading;
53 }
54
55     return 0;
56 }
```

This code focuses on eliminating the buffeting of button. We define several variables to save the state of LED and button. Then read the button state in while () constantly, and determine whether the state has changed. If it is changed, then this time point is recorded.

```

reading = digitalRead(buttonPin); //read the current state of button
if( reading != lastbuttonState){
    lastChangeTime = millis();
}
```

### millis()

This returns a number representing the number of milliseconds since your program called one of the wiringPiSetup functions. It returns an unsigned 32-bit number which wraps after 49 days.

Then according to just recorded time point, judge the duration of the button state change. If the duration exceeds captureTime (buffeting time) we set, it indicates that the state of the button has changed. During that time, the while () is still detecting the state of the button, so if there is a change, the time point of change will be updated. Then duration will be judged again until the duration of there is a stable state exceeds the time we set.

```
if(millis() - lastChangeTime > captureTime) {  
    //if button state is changed ,update the data.  
    if(reading != buttonState) {  
        buttonState = reading;
```

Finally, judge the state of Button. And if it is low level, the changing state indicates that the button is pressed, if the state is high level, then the button is released. Here, we change the status of the LED variable, and then update the state of LED.

```
if(buttonState == LOW) {  
    printf("Button is pressed!\n");  
    ledState = !ledState; //Reverse the LED state  
    if(ledState){  
        printf("turn on LED ... \n");  
    }  
    else {  
        printf("turn off LED ... \n");  
    }  
}  
//if the state is high, it means the action is releasing  
else {  
    printf("Button is released!\n");  
}
```

### Python Code 2.2.1 Tablelamp

First observe the project result, and then view the code.

If you have any concerns, please contact us via: support@freenove.com

1. Use cd command to enter 02.2.1\_Tablelamp directory of Python code

```
cd ~/Freenove_Kit/Code/Python_Code/02.2.1_Tablelamp
```

2. Use python command to execute python code "Tablelamp.py".

```
python Tablelamp.py
```

When the program is executed, press the Button once, then LED is turned on. Press the Button another time, then LED is turned off.

```

1 import RPi.GPIO as GPIO
2
3 ledPin = 11      # define ledPin
4 buttonPin = 12    # define buttonPin
5 ledState = False
6
7 def setup():
8     GPIO.setmode(GPIO.BOARD)      # use PHYSICAL GPIO Numbering
9     GPIO.setup(ledPin, GPIO.OUT)    # set ledPin to OUTPUT mode
10    GPIO.setup(buttonPin, GPIO.IN, pull_up_down=GPIO.PUD_UP)    # set buttonPin to PULL UP
11    INPUT mode
12
13 def buttonEvent(channel): # When button is pressed, this function will be executed
14     global ledState
15     print ('buttonEvent GPIO%d' %channel)
16     ledState = not ledState
17     if ledState :
18         print ('Led turned on >>>')
19     else :
20         print ('Led turned off <<<')
21     GPIO.output(ledPin, ledState)
22
23 def loop():
24     #Button detect
25     GPIO.add_event_detect(buttonPin,GPIO.FALLING,callback = buttonEvent,bouncetime=300)
26     while True:
27         pass
28
29 def destroy():
30     GPIO.cleanup()                  # Release GPIO resource
31
32 if __name__ == '__main__':      # Program entrance
33     print ('Program is starting...')
34     setup()
35     try:

```

```
36     loop()
37 except KeyboardInterrupt: # Press ctrl-c to end the program.
38     destroy()
```

RPi.GPIO provides us with a simple and effective function to eliminate the jitter, that is GPIO.add\_event\_detect(). It uses callback function. Once it detect that the buttonPin has a specified action FALLING, execute the specified function buttonEvent(). In the function buttonEvent, each time the ledState is reversed, the state of the LED will be updated.

```
def buttonEvent(channel): # When button is pressed, this function will be executed
    global ledState
    print ('buttonEvent GPIO%d' %channel)
    ledState = not ledState
    if ledState :
        print ('Led turned on >>>')
    else :
        print ('Led turned off <<<')
    GPIO.output(ledPin, ledState)

def loop():
    #Button detect
    GPIO.add_event_detect(buttonPin, GPIO.FALLING, callback = buttonEvent, bouncetime=300)
    while True:
        pass
```

Of course, you can also use the same programming idea of C code above to achieve this goal.

### **GPIO.add\_event\_detect(channel, GPIO.RISING, callback=my\_callback, bouncetime=200)**

This is an event detection function. The first parameter specifies the IO port to be detected. The second parameter specifies the action to be detected. The third parameter specified a function name, the function will be executed when the specified action is detected. And the fourth parameter is used to set the jitter time.

# Chapter 3 LEDBar Graph

We have learned how to control a LED blinking, and next we will learn how to control a number of LED.

## Project 3.1 Flowing Water Light

In this project, we use a number of LED to make a flowing water light.

### Component List

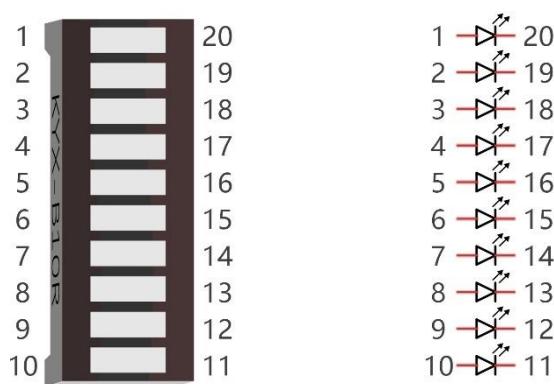

Raspberry Pi (with 40 GPIO) x1 GPIO Extension Board & Wire x1 BreadBoard x1	LED bar graph x1	Resistor 220Ω x10
Jumper 		

### Component knowledge

Let us learn about the basic features of components to use them better.

#### LED bar graph

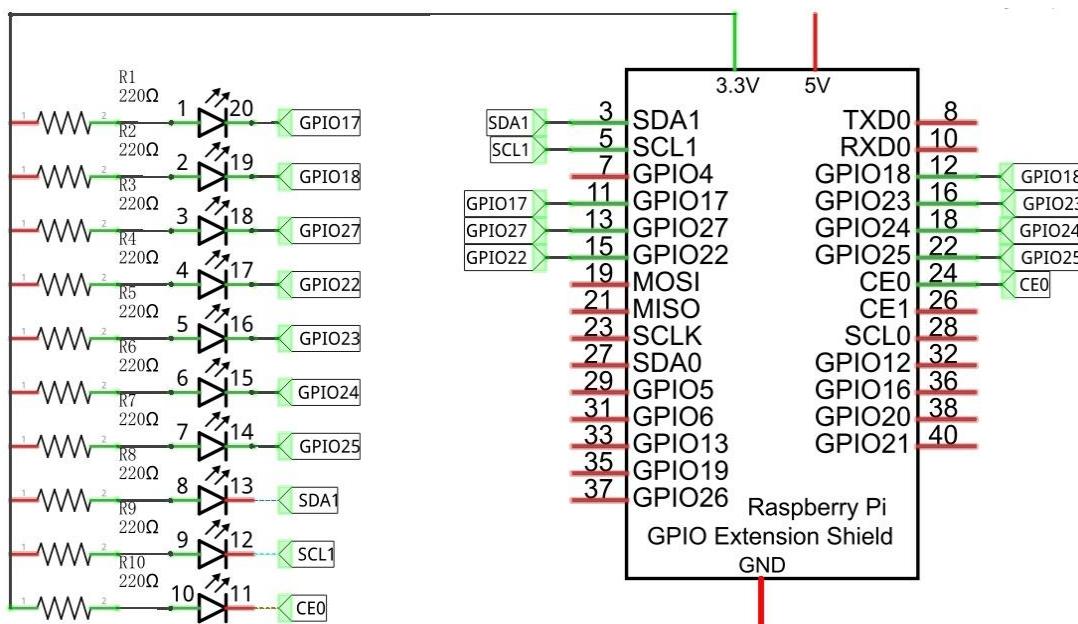

LED bar graph is a component Integration consist of 10 LEDs. There are two rows of pins at its bottom.

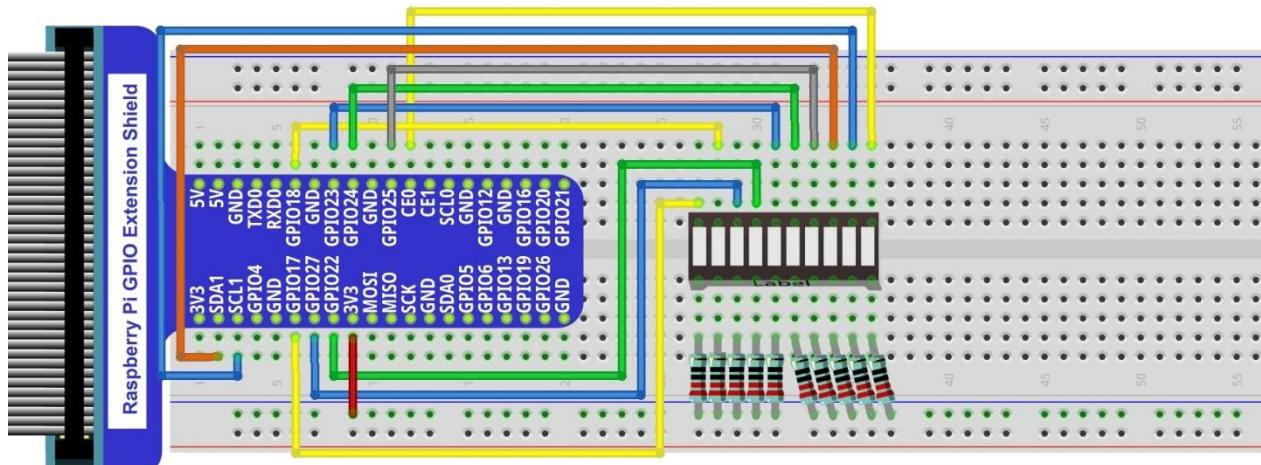

## Circuit

The network label is used in the circuit diagram below, and the pins with the same network label are connected together.

Schematic diagram

Hardware connection. If you need any support, please feel free to contact us via: [support@freenove.com](mailto:support@freenove.com)

In this circuit, the cathode of LED is connected to GPIO, which is the different from the previous circuit. So, LED will be turned on when GPIO output low level in the program.

## Code

This project is designed to make a water lamp. First turn on the first LED, then turn off it. Then turn on the second LED, and then turn off it..... Until the last LED is turned on, then is turned off. And repeats the process to achieve the effect of flowing water light.

### C Code 3.1.1 LightWater

First observe the project result, and then view the code.

**If you have any concerns, please contact us via: support@freenove.com**

1. Use cd command to enter 03.1.1\_LightWater directory of C code.

```
cd ~/Freenove_Kit/Code/C_Code/03.1.1_LightWater
```

2. Use following command to compile "LightWater.c" and generate executable file "LightWater".

```
gcc LightWater.c -o LightWater -lwiringPi
```

3. Then run the generated file "LightWater".

```
sudo ./LightWater
```

After the program is executed, you will see that LEDBar Graph starts with the flowing water way to be turned on from left to right, and then from right to left.

The following is the program code:

```

1 #include <wiringPi.h>
2 #include <stdio.h>
3
4 #define ledCounts 10
5 int pins[ledCounts] = {0, 1, 2, 3, 4, 5, 6, 8, 9, 10} ;
6
7 void main(void)
8 {
9     int i;
10    printf("Program is starting ... \n");
11
12    wiringPiSetup() ; //Initialize wiringPi.
13
14    for(i=0;i<ledCounts;i++) {      //Set pinMode for all led pins to output
15        pinMode(pins[i], OUTPUT);
16    }
17    while(1) {
18        for(i=0;i<ledCounts;i++) { // move led(on) from left to right
19            digitalWrite(pins[i], LOW);
20            delay(100);
21            digitalWrite(pins[i], HIGH);
22        }
23        for(i=ledCounts-1;i>-1;i--) { // move led(on) from right to left
24            digitalWrite(pins[i], LOW);
25            delay(100);
26            digitalWrite(pins[i], HIGH);
}

```

```

27     }
28 }
29 }
```

In the program, configure the GPIO0-GPIO9 to output mode. Then, in the endless “while” loop of main function, use two “for” loop to realize flowing water light from left to right and from right to left.

```

while(1) {
    for(i=0;i<ledCounts;i++) { // move led(on) from left to right
        digitalWrite(pins[i], LOW);
        delay(100);
        digitalWrite(pins[i], HIGH);
    }
    for(i=ledCounts-1;i>-1;i--) { // move led(on) from right to left
        digitalWrite(pins[i], LOW);
        delay(100);
        digitalWrite(pins[i], HIGH);
    }
}
```

### Python Code 3.1.1 LightWater

First observe the project result, and then view the code.

If you have any concerns, please contact us via: support@freenove.com

1. Use cd command to enter 03.1.1\_LightWater directory of Python code.

**cd ~/Freenove\_Kit/Code/Python\_Code/03.1.1\_LightWater**

2. Use Python command to execute Python code “LightWater.py”.

**python LightWater.py**

After the program is executed, you will see that LEDBar Graph starts with the flowing water way to be turned on from left to right, and then from right to left.

The following is the program code:

```

1 import RPi.GPIO as GPIO
2 import time
3
4 ledPins = [11, 12, 13, 15, 16, 18, 22, 3, 5, 24]
5
6 def setup():
7     GPIO.setmode(GPIO.BOARD)      # use PHYSICAL GPIO Numbering
8     GPIO.setup(ledPins, GPIO.OUT)  # set all ledPins to OUTPUT mode
9     GPIO.output(ledPins, GPIO.HIGH) # make all ledPins output HIGH level, turn off all led
10
11 def loop():
12     while True:
13         for pin in ledPins:      # make led(on) move from left to right
14             GPIO.output(pin, GPIO.LOW)
```

```

15         time.sleep(0.1)
16         GPIO.output(pin, GPIO.HIGH)
17     for pin in ledPins[::-1]:      # make led(on) move from right to left
18         GPIO.output(pin, GPIO.LOW)
19         time.sleep(0.1)
20         GPIO.output(pin, GPIO.HIGH)
21
22 def destroy():
23     GPIO.cleanup()                  # Release all GPIO
24
25 if __name__ == '__main__':        # Program entrance
26     print ('Program is starting...')
27     setup()
28     try:
29         loop()
30     except KeyboardInterrupt:    # Press ctrl-c to end the program.
31         destroy()

```

In the program, first define 10 pins connected to LED, and set them to output mode in subfunction `setup()`. Then in the `loop()` function, use two “for” loops to realize flowing water light from right to left and from left to right. Among them, `ledPins[::-1]` is used to traverse elements of `ledPins` in reverse order.

```

def loop():
    while True:
        for pin in ledPins:          #make led on from left to right
            GPIO.output(pin, GPIO.LOW)
            time.sleep(0.1)
            GPIO.output(pin, GPIO.HIGH)
        for pin in ledPins[::-1]:    #make led on from right to left
            GPIO.output(pin, GPIO.LOW)
            time.sleep(0.1)
            GPIO.output(pin, GPIO.HIGH)

```

# Chapter 4 Analog & PWM

In previous study, we have known that one button has two states: pressed and released, and LED has light-on/off state, then how to enter a middle state? How to output an intermediate state to let LED "semi bright"? That's what we're going to learn.

First, let's learn how to control the brightness of a LED.

## Project 4.1 Breathing LED

Breathing light, that is, LED is turned from off to on gradually, gradually from on to off, just like "breathing". So, how to control the brightness of a LED? We will use PWM to achieve this goal.

### Component List

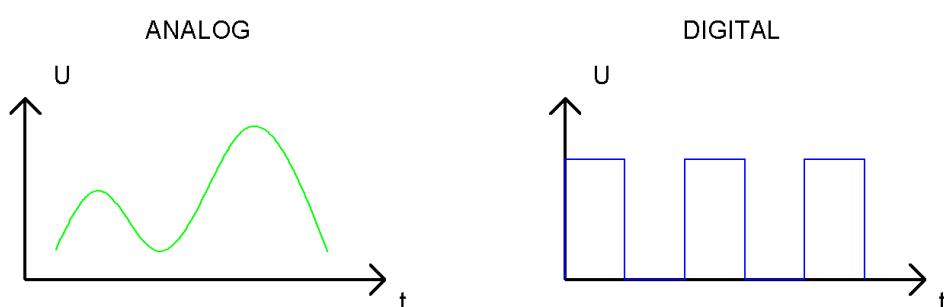

Raspberry Pi (with 40 GPIO) x1 GPIO Extension Board & Wire x1 BreadBoard x1	LED x1	Resistor 220Ω x1
Jumper 		

### Circuit knowledge

#### Analog & Digital

The analog signal is a continuous signal in time and value. On the contrary, digital signal is a discrete signal in time and value. Most signals in life are analog signals, for example, the temperature in one day is continuously changing, and will not appear a sudden change directly from 0°C to 10°C, while the digital signal is a jump change, which can be directly from 1 to 0.

Their difference can be illustrated by the following figure.

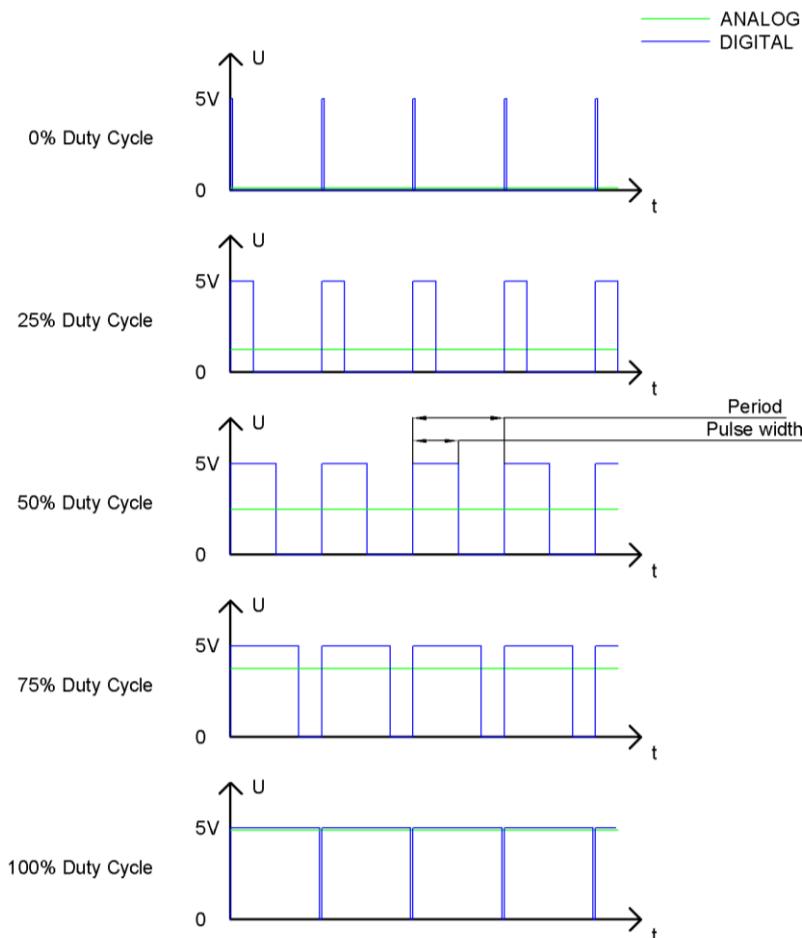

In practical application, we often use binary signal as digital signal, that is 0 and 1. The binary signal only has two forms (0 or 1), so it has strong stability. And digital signal and analog signal can be converted to each other.

### PWM

PWM, namely Pulse-Width Modulation, is a very effective technique for using digital signals to control analog circuits. The common processors can not directly output analog signals. PWM technology make it very convenient to achieve this purpose.

PWM technology uses digital pins to send certain frequency of square waves, that is, the output of high level and low level that last for a while alternately. The total time for each set of high level and low level is generally fixed, which is called period (the reciprocal of the period is frequency). The time of high level outputting is generally called pulse width, and the percentage of pulse width is called duty cycle.

The longer the output of high level last, the larger the duty cycle and the larger the corresponding voltage in analog signal will be. The following figures show how the analog signals voltage vary between 0V-5V (high level is 5V) corresponding to the pulse width 0%-100%:

The larger PWM duty cycle is, the larger the output power will be. So we can use PWM to control the brightness of LED, the speed of DC motor and so on.

It is evident from the above that PWM is not real analog, and the effective value of the voltage is equivalent to the corresponding analog. so, we can control the output power of the LED and other output modules to achieve different effects.

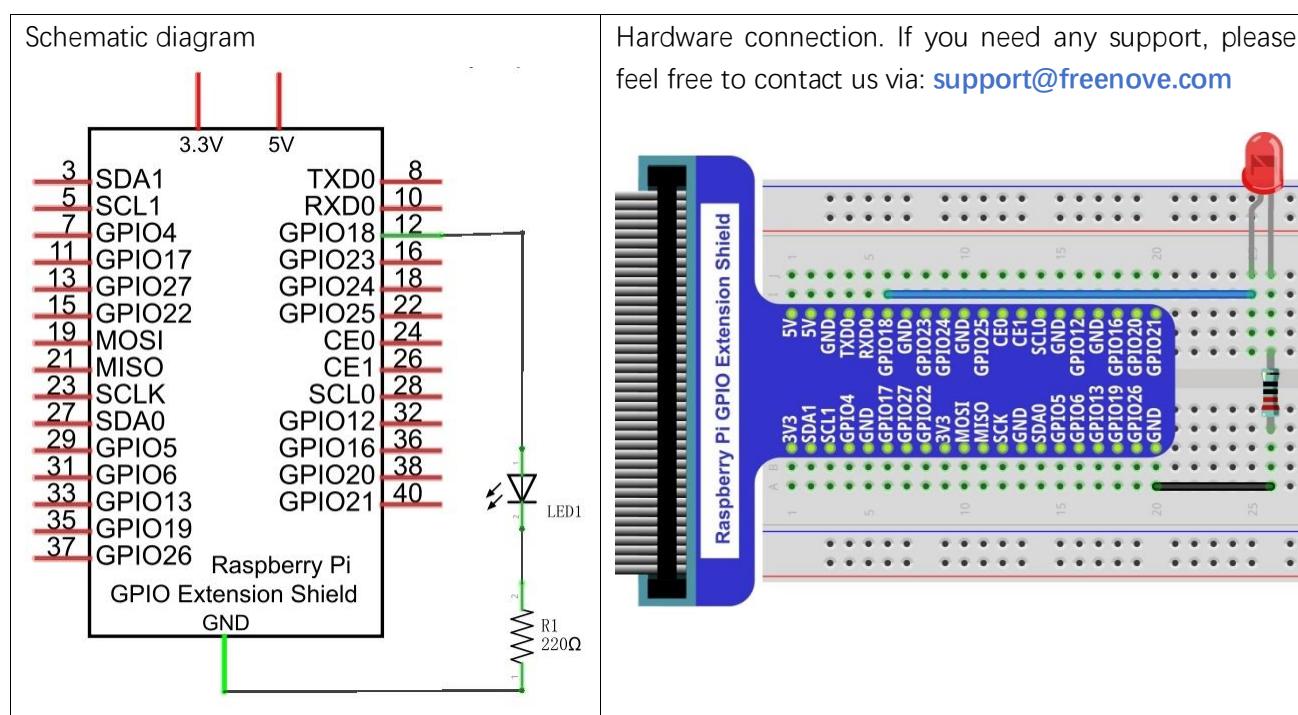

In RPi, only GPIO18 has the ability to output hardware PWM with a 10-bit accuracy, that is, 100% of the pulse width can be divided into  $2^{10}=1024$  equal parts.

The wiringPi library of C provides a hardware PWM method and a software PWM method, while wiringPi library of Python doesn't provide hardware PWM method. There is only software PWM for Python.

The hardware PWM only needs to be configured, does not occupy CPU resources, and is more precise in time control. The software PWM requires the CPU to work all the time, using the code to output high level and low level. This part of the code is carried out in multi-thread, and the time precision is relatively not high enough.

In order to keep the running results consistent, we adopt the way of software PWM.

## Circuit

## Code

This project is designed to make PWM output GPIO18 with pulse width increasing from 0% to 100%, and then reducing from 100% to 0% gradually.

### C Code 4.1.1 BreathingLED

First observe the project result, and then view the code.

If you have any concerns, please contact us via: [support@freenove.com](mailto:support@freenove.com)

1. Use cd command to enter 04.1.1\_BreathingLED directory of C code.

```
cd ~/Freenove_Kit/Code/C_Code/04.1.1_BreathingLED
```

2. Use following command to compile "BreathingLED.c" and generate executable file "BreathingLED".

```
gcc BreathingLED.c -o BreathingLED -lwiringPi
```

3. Then run the generated file "BreathingLED"

```
sudo ./BreathingLED
```

After the program is executed, you'll see that LED is turned from on to off and then from off to on gradually

like breathing.

The following is the program code:

```

1 #include <wiringPi.h>
2 #include <stdio.h>
3 #include <softPwm.h>
4
5 #define ledPin    1
6
7 void main(void)
8 {
9     int i;
10
11     printf("Program is starting ... \n");
12
13     wiringPiSetup(); //Initialize wiringPi.
14
15     softPwmCreate(ledPin, 0, 100); //Create SoftPWM pin
16
17     while(1) {
18         for(i=0;i<100;i++) { //make the led brighter
19             softPwmWrite(ledPin, i);
20             delay(20);
21         }
22         delay(300);
23         for(i=100;i>=0;i--) { //make the led darker
24             softPwmWrite(ledPin, i);
25             delay(20);
26         }
27         delay(300);
28     }
29 }
```

First, create a software PWM pin.

```
softPwmCreate(ledPin, 0, 100); //Create SoftPWM pin
```

There are two “for” loops in the next endless “while” loop. The first makes the ledPin output PWM from 0% to 100% and the second makes the ledPin output PWM from 100% to 0%.

```

while(1) {
    for(i=0;i<100;i++) {
        softPwmWrite(ledPin, i);
        delay(20);
    }
    delay(300);
    for(i=100;i>=0;i--) {
        softPwmWrite(ledPin, i);
        delay(20);
    }
}
```

```

        }
        delay(300);
    }
}

```

You can also adjust the rate of the state change of LED by changing the parameters of the delay() function in the “for” loop.

**int softPwmCreate (int pin, int initialValue, int pwmRange);**

This creates a software controlled PWM pin.

**void softPwmWrite (int pin, int value);**

This updates the PWM value on the given pin.

For more details, please refer <http://wiringpi.com/reference/software-pwm-library/>

#### Python Code 4.1.1 BreathingLED

First observe the project result, and then view the code.

If you have any concerns, please contact us via: [support@freenove.com](mailto:support@freenove.com)

1. Use cd command to enter 04.1.1\_BreathingLED directory of Python code.

**cd ~/Freenove\_Kit/Code/Python\_Code/04.1.1\_BreathingLED**

2. Use python command to execute python code “BreathingLED.py”.

**python BreathingLED.py**

After the program is executed, you'll see that LED is turned from on to off and then from off to on gradually like breathing.

The following is the program code:

```

1 import RPi.GPIO as GPIO
2
3
4 LedPin = 12      # define the LedPin
5
6 def setup():
7     global p
8     GPIO.setmode(GPIO.BOARD)      # use PHYSICAL GPIO Numbering
9     GPIO.setup(LedPin, GPIO.OUT)   # set LedPin to OUTPUT mode
10    GPIO.output(LedPin, GPIO.LOW)  # make ledPin output LOW level to turn off LED
11
12    p = GPIO.PWM(LedPin, 500)    # set PWM Frequency to 500Hz
13    p.start(0)                  # set initial Duty Cycle to 0
14
15 def loop():
16     while True:
17         for dc in range(0, 101, 1):  # make the led brighter
18             p.ChangeDutyCycle(dc)    # set dc value as the duty cycle
19             time.sleep(0.01)
20             time.sleep(1)
21         for dc in range(100, -1, -1): # make the led darker
22             p.ChangeDutyCycle(dc)    # set dc value as the duty cycle
23             time.sleep(0.01)

```

```

24         time.sleep(1)
25
26     def destroy():
27         p.stop() # stop PWM
28         GPIO.cleanup() # Release all GPIO
29
30     if __name__ == '__main__':    # Program entrance
31         print ('Program is starting ... ')
32         setup()
33         try:
34             loop()
35         except KeyboardInterrupt: # Press ctrl-c to end the program.
36             destroy()

```

LED is connected to the IO port called GPIO18. And LedPin is defined as 12 and set to output mode according to the corresponding chart for pins. Then create a PWM instance and set the PWM frequency to 1000HZ, the initial duty cycle to 0%.

```

LedPin = 12      # define the LedPin

def setup():
    global p
    GPIO.setmode(GPIO.BOARD)      # use PHYSICAL GPIO Numbering
    GPIO.setup(LedPin, GPIO.OUT)   # set LedPin to OUTPUT mode
    GPIO.output(LedPin, GPIO.LOW)  # make ledPin output LOW level to turn off LED

    p = GPIO.PWM(LedPin, 500)     # set PWM Frequency to 500Hz
    p.start(0)                   # set initial Duty Cycle to 0

```

There are two “for” loops used to realize breathing LED in the next endless “while” loop. The first makes the ledPin output PWM from 0% to 100% and the second makes the ledPin output PWM from 100% to 0%.

```

def loop():
    while True:
        for dc in range(0, 101, 1):  # make the led brighter
            p.ChangeDutyCycle(dc)    # set dc value as the duty cycle
            time.sleep(0.01)
        time.sleep(1)
        for dc in range(100, -1, -1): # make the led darker
            p.ChangeDutyCycle(dc)    # set dc value as the duty cycle
            time.sleep(0.01)
        time.sleep(1)

```

The related functions of PWM are described as follows:

**p = GPIO.PWM(channel, frequency)**

To create a PWM instance:

**p.start(dc)**

To start PWM:, where dc is the duty cycle ( $0.0 \leq dc \leq 100.0$ )

**p.ChangeFrequency(freq)**

To change the frequency, where freq is the new frequency in Hz

**p.ChangeDutyCycle(dc)**

To change the duty cycle, where  $0.0 \leq dc \leq 100.0$

**p.stop()**

To stop PWM.

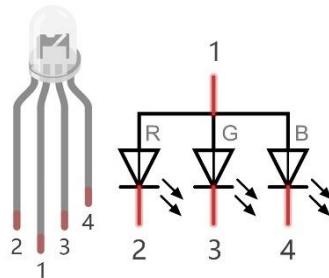

For more details about usage method for PWM of RPi.GPIO, please refer to:

<https://sourceforge.net/p/raspberry-gpio-python/wiki/PWM/>

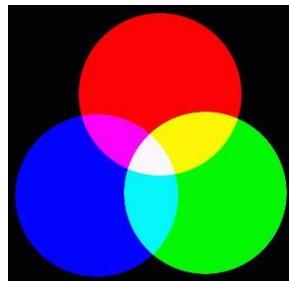

# Chapter 5 RGBLED

In this chapter, we will learn how to control a RGBLED.

RGB LED has integrated 3 LEDs that can respectively emit red, green and blue light. And it has 4 pins. The long pin (1) is the common port, that is, 3 LED's positive or negative port. The RGB LED with common positive port and its symbol are shown below. We can make RGB LED emit various colors of light by controlling these 3 LEDs to emit light with different brightness,

Red, green, and blue light are called 3 primary colors. When you combine these three primary-color light with different brightness, it can produce almost all kinds of visible lights. Computer screens, single pixel of cell phone screen, neon, and etc. are working under this principle.

RGB

If we use three 8 bit PWM to control the RGBLED, in theory, we can create  $2^8 * 2^8 * 2^8 = 16777216$  (16 million) color through different combinations.

Next, we will use RGBLED to make a colorful LED.

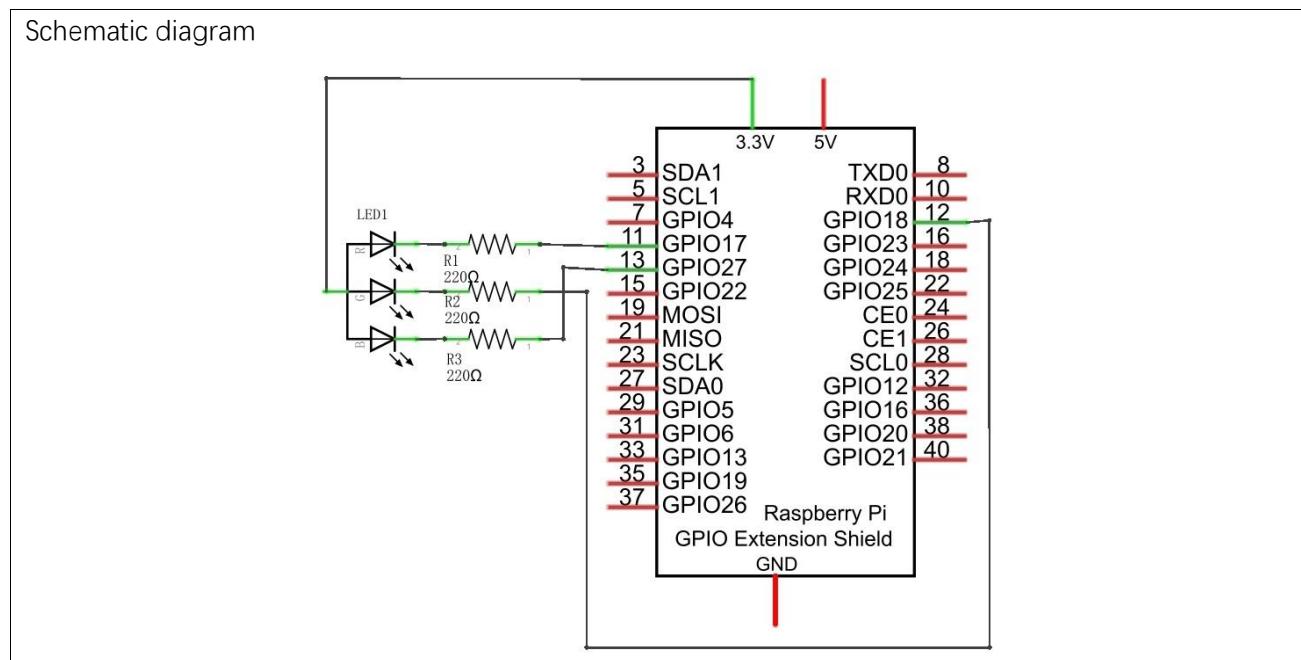

## Project 5.1 Colorful LED

In this project, we will make a colorful LED. And we can control RGBLED to switch different colors automatically.

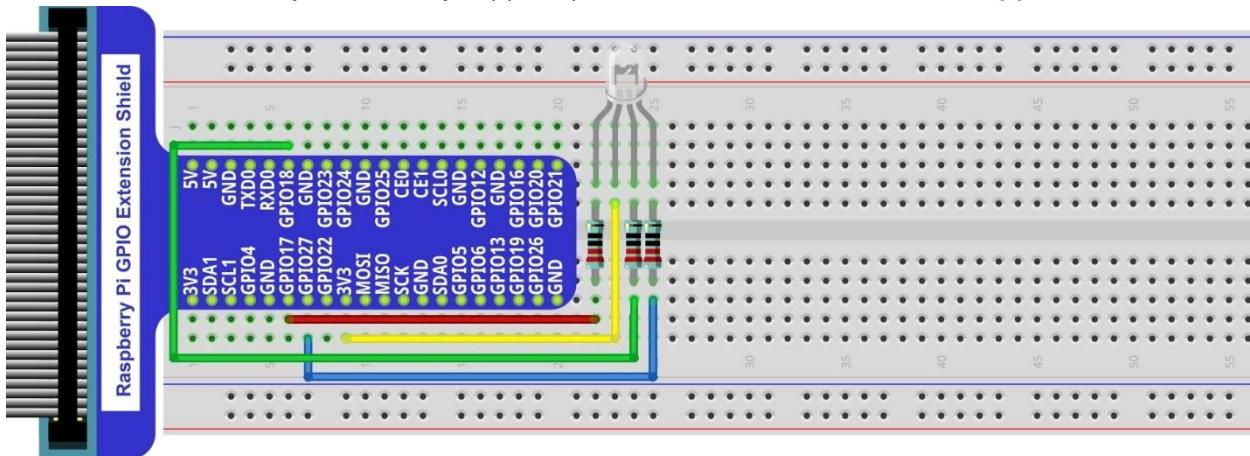

## Component List

Raspberry Pi (with 40 GPIO) x1 GPIO Extension Board & Wire x1 BreadBoard x1	RGBLED x1	Resistor 220Ω x3
Jumper		

## Circuit

Hardware connection. If you need any support, please feel free to contact us via: [support@freenove.com](mailto:support@freenove.com)

In this kit, the RGB led is **Common anode**. The **voltage difference** between LED will make it work.

## Code

Since this project requires 3 PWM, but in RPi, only one GPIO has the hardware capability to output PWM, we need to use the software to make the ordinary GPIO output PWM.

### C Code 5.1.1 ColorfulLED

First observe the project result, and then view the code.

If you have any concerns, please contact us via: [support@freenove.com](mailto:support@freenove.com)

1. Use cd command to enter 05.1.1\_ColorfulLED directory of C code.

```
cd ~/Freenove_Kit/Code/C_Code/05.1.1_ColorfulLED
```

2. Use following command to compile "ColorfulLED.c" and generate executable file "ColorfulLED". Note: in this project, the software PWM uses a multi-threading mechanism. So "-lpthread" option need to be add the compiler.

```
gcc ColorfulLED.c -o ColorfulLED -lwiringPi -lpthread
```

3. And then run the generated by "ColorfulLED".

```
sudo ./ColorfulLED
```

After the program is executed, you will see that the RGBLED shows light of different color randomly.

The following is the program code:

```

1 #include <wiringPi.h>
2 #include <softPwm.h>
3 #include <stdio.h>
4 #include <stdlib.h>
5
6 #define ledPinRed    0
7 #define ledPinGreen   1
8 #define ledPinBlue    2
9
10 void setupLedPin(void)
11 {
12     softPwmCreate(ledPinRed, 0, 100); //Creat SoftPWM pin for red
13     softPwmCreate(ledPinGreen, 0, 100); //Creat SoftPWM pin for green
14     softPwmCreate(ledPinBlue, 0, 100); //Creat SoftPWM pin for blue
15 }
16
17 void setLedColor(int r, int g, int b)
18 {
19     softPwmWrite(ledPinRed, r); //Set the duty cycle
20     softPwmWrite(ledPinGreen, g); //Set the duty cycle
21     softPwmWrite(ledPinBlue, b); //Set the duty cycle
22 }
23
24 int main(void)
25 {
26     int r, g, b;
```

```

27
28     printf("Program is starting ... \n");
29
30     wiringPiSetup(); //Initialize wiringPi.
31
32     setupLedPin();
33     while(1) {
34         r=random()%100; //get a random in (0, 100)
35         g=random()%100; //get a random in (0, 100)
36         b=random()%100; //get a random in (0, 100)
37         setLedColor(r, g, b); //set random as the duty cycle value
38         printf("r=%d, g=%d, b=%d \n", r, g, b);
39         delay(300);
40     }
41     return 0;
42 }
```

First, in subfunction of ledInit(), create the software PWM control pins used to control the R, G, B pin respectively.

```

void setupLedPin(void)
{
    softPwmCreate(ledPinRed, 0, 100); //Creat SoftPWM pin for red
    softPwmCreate(ledPinGreen, 0, 100); //Creat SoftPWM pin for green
    softPwmCreate(ledPinBlue, 0, 100); //Creat SoftPWM pin for blue
}
```

Then create subfunction, and set the PWM of three pins.

```

void setLedColor(int r, int g, int b)
{
    softPwmWrite(ledPinRed, r); //Set the duty cycle
    softPwmWrite(ledPinGreen, g); //Set the duty cycle
    softPwmWrite(ledPinBlue, b); //Set the duty cycle
}
```

Finally, in the “while” loop of main function, get three random numbers and specify them as the PWM duty cycle, which will be assigned to the corresponding pins. So RGBLED can switch the color randomly all the time.

```

while(1) {
    r=random()%100; //get a random in (0, 100)
    g=random()%100; //get a random in (0, 100)
    b=random()%100; //get a random in (0, 100)
    setLedColor(r, g, b); //set random as the duty cycle value
    printf("r=%d, g=%d, b=%d \n", r, g, b);
    delay(300);
}
```

The related function of Software PWM can be described as follows:

**long random();**

This function will return a random number.

For more details about Software PWM, please refer to: <http://wiringpi.com/reference/software-pwm-library/>

### Python Code 5.1.1 ColorfulLED

First observe the project result, and then view the code.

**If you have any concerns, please contact us via: support@freenove.com**

1. Use cd command to enter 05.1.1\_ColorfullLED directory of Python code.

**cd ~/Freenove\_Kit/Code/Python\_Code/05.1.1\_ColorfullLED**

2. Use python command to execute python code "ColorfullLED.py".

**python ColorfullLED.py**

After the program is executed, you will see that the RGBLED shows light of different color randomly.

The following is the program code:

```

1 import RPi.GPIO as GPIO
2 import time
3 import random
4
5 pins = {'pinRed':11, 'pinGreen':12, 'pinBlue':13} # define the pins for RGBLED
6
7 def setup():
8     global pwmRed, pwmGreen, pwmBlue
9     GPIO.setmode(GPIO.BOARD)      # use PHYSICAL GPIO Numbering
10    GPIO.setup(pins, GPIO.OUT)    # set RGBLED pins to OUTPUT mode
11    GPIO.output(pins, GPIO.HIGH)  # make RGBLED pins output HIGH level
12    pwmRed = GPIO.PWM(pins['pinRed'], 2000)    # set PWM Frequnce to 2kHz
13    pwmGreen = GPIO.PWM(pins['pinGreen'], 2000)  # set PWM Frequnce to 2kHz
14    pwmBlue = GPIO.PWM(pins['pinBlue'], 2000)    # set PWM Frequnce to 2kHz
15    pwmRed.start(0)        # set initial Duty Cycle to 0
16    pwmGreen.start(0)
17    pwmBlue.start(0)
18
19 def setColor(r_val,g_val,b_val):      # change duty cycle for three pins to r_val,g_val,b_val
20     pwmRed.ChangeDutyCycle(r_val)       # change pwmRed duty cycle to r_val
21     pwmGreen.ChangeDutyCycle(g_val)
22     pwmBlue.ChangeDutyCycle(b_val)
23
24 def loop():
25     while True :
26         r=random.randint(0,100)  #get a random in (0,100)
27         g=random.randint(0,100)
28         b=random.randint(0,100)
29         setColor(r, g, b)        #set random as a duty cycle value

```

```

30         print (' r=%d, g=%d, b=%d ' %(r ,g, b))
31         time.sleep(0.3)
32
33     def destroy():
34         pwmRed.stop()
35         pwmGreen.stop()
36         pwmBlue.stop()
37         GPIO.cleanup()
38
39     if __name__ == '__main__':      # Program entrance
40         print (' Program is starting ... ')
41         setup()
42         try:
43             loop()
44         except KeyboardInterrupt: # Press ctrl-c to end the program.
45             destroy()

```

In last chapter, we have learned how to use python language to make a pin output PWM. In this project, we let three pins output PWM, and the usage is exactly the same as last chapter. In the while loop of "loop" function, we first obtain three random numbers, and then specify these three random numbers as the PWM value of the three pins so that the RGBLED switching of different colors randomly.

```

def loop():
    while True :
        r=random.randint(0,100) #get a random in (0,100)
        g=random.randint(0,100)
        b=random.randint(0,100)
        setColor(r,g,b)          #set random as a duty cycle value
        print (' r=%d, g=%d, b=%d ' %(r ,g, b))
        time.sleep(0.3)

```

About function randint():

**random.randint(a, b)**

The function can returns a random integer within the specified range (a, b).

# Chapter 6 Buzzer

In this chapter, we will learn a component that can sound, buzzer.

## Project 6.1 Doorbell

We will make this kind of doorbell: when the button is pressed, the buzzer sounds; and when the button is released, the buzzer stops sounding.

## Component List

Raspberry Pi (with 40 GPIO) x1 GPIO Extension Board & Wire x1 BreadBoard x1	Jumper 			
NPN transistor x1 (S8050) 	Active buzzer x1 	Push button x1 	Resistor 1kΩ x1 	Resistor 10kΩ x2 

## Component knowledge

### Buzzer

Buzzer is a sounding component, which is widely used in electronic devices such as calculator, electronic warning clock, alarm. Buzzer has active and passive type. Active buzzer has oscillator inside, and it will sound as long as it is supplied with power. Passive buzzer requires external oscillator signal (generally use PWM with different frequency) to make a sound.

Active buzzer is easy to use. Generally, it can only make a specific frequency of sound. Passive buzzer requires an external circuit to make a sound, but it can be controlled to make a sound with different frequency. The resonant frequency of the passive buzzer is 2kHz, which means the passive buzzer is loudest when its resonant frequency is 2kHz.

Next, we will use an active buzzer to make a doorbell and a passive buzzer to make an alarm.

### How to identify active and passive buzzer?

1. Usually, there is a label on the surface of active buzzer covering the vocal hole, but this is not an absolute judgment method.
2. Active buzzer is more complex than passive buzzer in manufacture. There are a lot of circuits and crystal oscillator elements inside active buzzer, which are covered with a waterproof coating, around its pins. Passive buzzer doesn't have these coatings. From the pins of passive buzzer, you can even see the circuit board, coils, and permanent magnets directly.

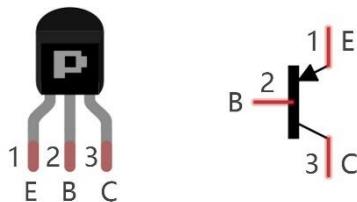

### Transistor

Due to the current operating of buzzer is so large that GPIO of RPi output capability can not meet the requirement. A transistor of NPN type is needed here to amplify the current.

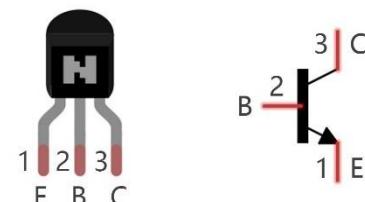

Transistor, the full name: semiconductor transistor, is a semiconductor device that controls current. Transistor can be used to amplify weak signal, or works as a switch. It has three electrodes(PINs): base (b), collector (c) and emitter (e). When there is current passing between "be", "ce" will allow several-fold current (transistor magnification) pass, at this point, transistor works in the amplifying area. When current between "be" exceeds a certain value, "ce" will not allow current to increase any longer, at this point, transistor works in the saturation area. Transistor has two types shown below: PNP and NPN,

PNP transistor

NPN transistor

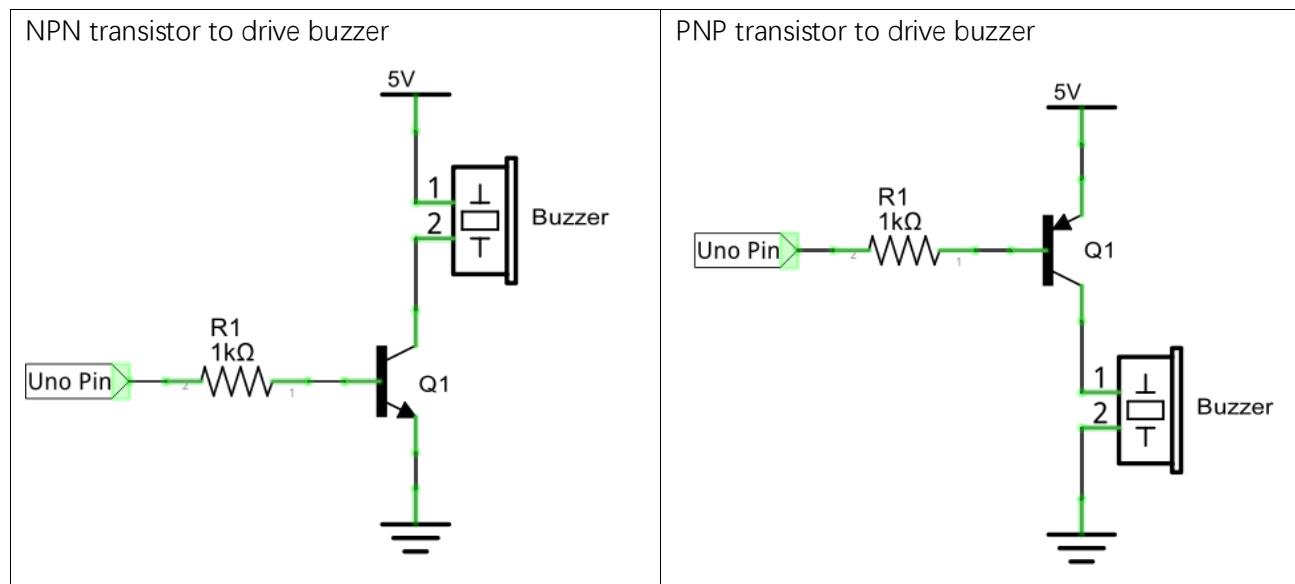

In our kit, the PNP transistor is marked with 8550, and the NPN transistor is marked with 8050.

According to the transistor's characteristics, it is often used as a switch in digital circuits. For micro-controller's capacity of output current is very weak, we will use transistor to amplify current and drive large-current components.

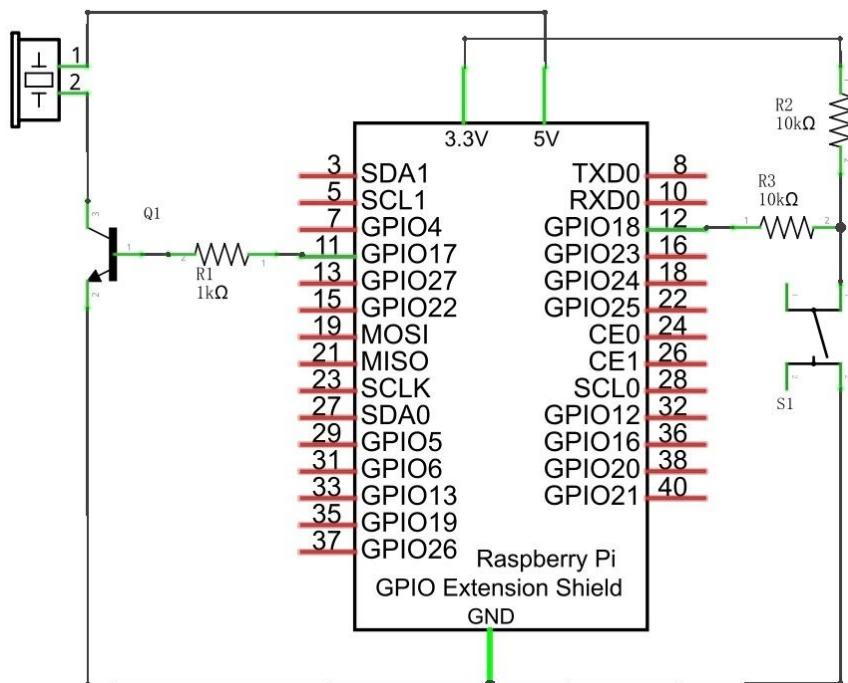

When use NPN transistor to drive buzzer, we often adopt the following method. If GPIO outputs high level, current will flow through R1, the transistor gets conducted, and the buzzer make a sound. If GPIO outputs low level, no current flows through R1, the transistor will not be conducted, and buzzer will not sound.

When use PNP transistor to drive buzzer, we often adopt the following method. If GPIO outputs low level, current will flow through R1, the transistor gets conducted, buzzer make a sound. If GPIO outputs high level, no current flows through R1, the transistor will not be conducted, and buzzer will not sound.

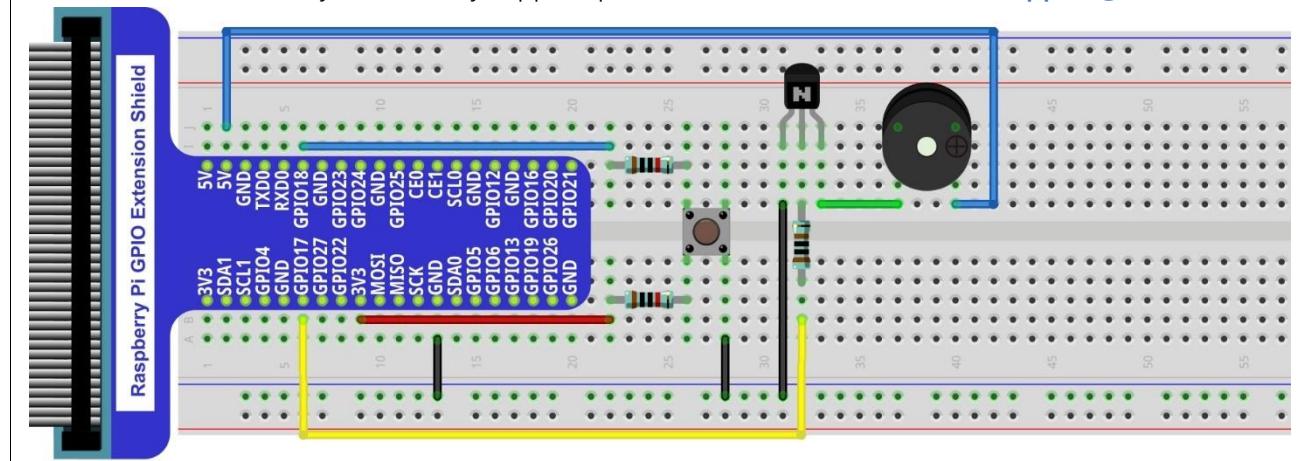

## Circuit

Schematic diagram

Hardware connection. If you need any support, please feel free to contact us via: [support@freenove.com](mailto:support@freenove.com)

Note: in this circuit, the power supply for buzzer is 5V, and pull-up resistor of the button connected to the power 3.3V. The buzzer can work when connected to power 3.3V, but it will reduce the loudness.

## Code

In this project, buzzer is controlled by the button. When the button is pressed, the buzzer sounds. And when the button is released, the buzzer stops sounding. In the logic, it is the same to using button to control LED.

### C Code 6.1.1 Doorbell

First observe the project result, and then view the code.

**If you have any concerns, please contact us via: support@freenove.com**

1. Use cd command to enter 06.1.1\_Doorbell directory of C code.

```
cd ~/Freenove_Kit/Code/C_Code/06.1.1_Doorbell
```

2. Use following command to compile "Doorbell.c" and generate executable file "Doorbell.c".

```
gcc Doorbell.c -o Doorbell -lwiringPi
```

3. Then run the generated file "Doorbell".

```
sudo ./Doorbell
```

After the program is executed, press the button, then buzzer sounds. And when the button is release, the buzzer will stop sounding.

The following is the program code:

```

1 #include <wiringPi.h>
2 #include <stdio.h>
3
4 #define buzzerPin 0 //define the buzzerPin
5 #define buttonPin 1 //define the buttonPin
6
7 void main(void)
8 {
9     printf("Program is starting ... \n");
10    wiringPiSetup();
11
12    pinMode(buzzerPin, OUTPUT);
13    pinMode(buttonPin, INPUT);
14
15    pullUpDnControl(buttonPin, PUD_UP); //pull up to HIGH level
16    while(1) {
17
18        if(digitalRead(buttonPin) == LOW){ //button is pressed
19            digitalWrite(buzzerPin, HIGH); //Turn on buzzer
20            printf("buzzer turned on >>> \n");
21        }
22        else { //button is released
23            digitalWrite(buzzerPin, LOW); //Turn off buzzer
24            printf("buzzer turned off <<< \n");
25        }
26    }
}
```

```

27 }
28 }
```

The code is exactly the same to using button to control LED logically. You can try to use the PNP transistor to achieve the function of his circuit once again.

#### Python Code 6.1.1 Doorbell

First observe the project result, then view the code.

**If you have any concerns, please contact us via: support@freenove.com**

1. Use cd command to enter 06.1.1\_Doorbell directory of Python code.

```
cd ~/Freenove_Kit/Code/Python_Code/06.1.1_Doorbell
```

2. Use python command to execute python code "Doorbell.py".

```
python Doorbell.py
```

After the program is executed, press the button, then buzzer sounds. And when the button is released, the buzzer will stop sounding.

The following is the program code:

```

1 import RPi.GPIO as GPIO
2
3 buzzerPin = 11      # define buzzerPin
4 buttonPin = 12      # define buttonPin
5
6 def setup():
7     GPIO.setmode(GPIO.BCM)          # use PHYSICAL GPIO Numbering
8     GPIO.setup(buzzerPin, GPIO.OUT)  # set buzzerPin to OUTPUT mode
9     GPIO.setup(buttonPin, GPIO.IN, pull_up_down=GPIO.PUD_UP)    # set buttonPin to PULL UP
10    INPUT mode
11
12 def loop():
13     while True:
14         if GPIO.input(buttonPin)==GPIO.LOW: # if button is pressed
15             GPIO.output(buzzerPin,GPIO.HIGH) # turn on buzzer
16             print ('buzzer turned on >>>')
17         else : # if button is released
18             GPIO.output(buzzerPin,GPIO.LOW) # turn off buzzer
19             print ('buzzer turned off <<<')
20
21 def destroy():
22     GPIO.cleanup()                  # Release all GPIO
23
24 if __name__ == '__main__':      # Program entrance
25     print ('Program is starting...')
26     setup()
27     try:
```

```

28     loop()
29     except KeyboardInterrupt: # Press ctrl-c to end the program.
30         destroy()

```

The code is exactly the same to using button to control LED logically. You can try to use the PNP transistor to achieve the function of his circuit once again.

## Project 6.2 Alarm

Next, we will use a passive buzzer to make an alarm.

Component list and the circuit part is the similar to last section. In the Doorbell circuit, only the active buzzer needs to be replaced with a passive buzzer.

### Code

In this project, the buzzer alarm is controlled by the button. Press the button, then buzzer sounds. If you release the button, the buzzer will stop sounding. In the logic, it is the same to using button to control LED. In the control method, passive buzzer requires PWM of certain frequency to sound.

#### C Code 6.2.1 Alertor

First, observe the project result, and then view the code.

**If you have any concerns, please contact us via: support@freenove.com**

1. Use cd command to enter 06.2.1\_Alertor directory of C code.

```
cd ~/Freenove_Kit/Code/C_Code/06.2.1_Alertor
```

2. Use following command to compile "Alertor.c" and generate executable file "Alertor". "-lm" and "-lpthread" compiler options are needed to add here.

```
gcc Alertor.c -o Alertor -lwiringPi -lm -lpthread
```

3. Then run the generated file "Alertor".

```
sudo ./Alertor
```

After the program is executed, press the button, then buzzer sounds. And when the button is release, the buzzer will stop sounding.

The following is the program code:

```

1 #include <wiringPi.h>
2 #include <stdio.h>
3 #include <softTone.h>
4 #include <math.h>
5
6 #define buzzerPin    0 //define the buzzerPin
7 #define buttonPin    1 //define the buttonPin
8
9 void alertor(int pin) {
10     int x;
11     double sinVal, toneVal;

```

```

12     for (x=0;x<360;x++) { // frequency of the alertor is consistent with the sine wave
13         sinVal = sin(x * (M_PI / 180));           //Calculate the sine value
14         toneVal = 2000 + sinVal * 500;           //Add the resonant frequency and weighted sine
15         value
16         softToneWrite(pin, toneVal);           //output corresponding PWM
17         delay(1);
18     }
19 }
20 void stopAlertor(int pin){
21     softToneWrite(pin, 0);
22 }
23 int main(void)
24 {
25     printf("Program is starting ... \n");
26
27     wiringPiSetup();
28
29     pinMode(buzzerPin, OUTPUT);
30     pinMode(buttonPin, INPUT);
31     softToneCreate(buzzerPin); //set buzzerPin
32     pullUpDnControl(buttonPin, PUD_UP); //pull up to HIGH level
33     while(1){
34         if(digitalRead(buttonPin) == LOW){ //button is pressed
35             alertor(buzzerPin); // turn on buzzer
36             printf("alertor turned on >> \n");
37         }
38         else { //button is released
39             stopAlertor(buzzerPin); // turn off buzzer
40             printf("alertor turned off << \n");
41         }
42     }
43     return 0;
44 }
```

The code is the same to the active buzzer logically, but the way to control the buzzer is different. Passive buzzer requires PWM of certain frequency to control, so you need to create a software PWM pin though softToneCreate (buzzeRPin). Here softTone is dedicated to generate square wave with variable frequency and duty cycle fixed to 50%, which is a better choice for controlling the buzzer.

	softToneCreate (buzzeRPin) ;
--	------------------------------

In the while loop of main function, when the button is pressed, subfunction alertor() will be called and the alertor will issue a warning sound. The frequency curve of the alarm is based on the sine curve. We need to calculate the sine value from 0 to 360 degree and multiply a certain value (here is 500) and plus the resonant frequency of buzzer. We can set the PWM frequency through softToneWrite (pin, toneVal).

```
void alertor(int pin){  
    int x;  
    double sinVal, toneVal;  
    for(x=0;x<360;x++){ //The frequency is based on the sine curve.  
        sinVal = sin(x * (M_PI / 180));  
        toneVal = 2000 + sinVal * 500;  
        softToneWrite(pin, toneVal);  
        delay(1);  
    }  
}
```

If you want to close the buzzer, just set PWM frequency of the buzzer pin to 0.

```
void stopAlertor(int pin){  
    softToneWrite(pin, 0);  
}
```

The related functions of softTone is described as follows:

**int softToneCreate (int pin) ;**

This creates a software controlled tone pin.

**void softToneWrite (int pin, int freq) ;**

This updates the tone frequency value on the given pin.

For more details about softTone, please refer to :<http://wiringpi.com/reference/software-tone-library/>

### Python Code 6.2.1 Alertor

First observe the project result, and then view the code.

**If you have any concerns, please contact us via: support@freenove.com**

1. Use cd command to enter 06.2.1\_Alertor directory of Python code.

**cd ~/Freenove\_Kit/Code/Python\_Code/06.2.1\_Alertor**

2. Use the python command to execute the Python code “Alertor.py”.

**python Alertor.py**

After the program is executed, press the button, then the buzzer sounds. When the button is released, the buzzer will stop sounding.

The following is the program code:

```
1 import RPi.GPIO as GPIO  
2 import time  
3 import math  
4  
5 buzzerPin = 11      # define the buzzerPin  
6 buttonPin = 12      # define the buttonPin
```

```
7
8 def setup():
9     global p
10    GPIO.setmode(GPIO.BOARD)          # Use PHYSICAL GPIO Numbering
11    GPIO.setup(buzzerPin, GPIO.OUT)   # set RGBLED pins to OUTPUT mode
12    GPIO.setup(buttonPin, GPIO.IN, pull_up_down=GPIO.PUD_UP)  # Set buttonPin to INPUT
13 mode, and pull up to HIGH level, 3.3V
14    p = GPIO.PWM(buzzerPin, 1)
15    p.start(0);
16
17 def loop():
18     while True:
19         if GPIO.input(buttonPin)==GPIO.LOW:
20             alertor()
21             print (' alertor turned on >>> ')
22         else :
23             stopAlertor()
24             print (' alertor turned off <<< ')
25 def alertor():
26     p.start(50)
27     for x in range(0,361):      # Make frequency of the alertor consistent with the sine wave
28         sinVal = math.sin(x * (math.pi / 180.0))          # calculate the sine value
29         toneVal = 2000 + sinVal * 500 # Add to the resonant frequency with a Weighted
30         p.ChangeFrequency(toneVal)      # Change Frequency of PWM to toneVal
31         time.sleep(0.001)
32
33 def stopAlertor():
34     p.stop()
35
36 def destroy():
37     GPIO.output(buzzerPin, GPIO.LOW)      # Turn off buzzer
38     GPIO.cleanup()                      # Release GPIO resource
39
40 if __name__ == '__main__':      # Program entrance
41     print (' Program is starting... ')
42     setup()
43     try:
44         loop()
45     except KeyboardInterrupt: # Press ctrl-c to end the program.
46         destroy()
```

The code is the same to the active buzzer logically, but the way to control the buzzer is different. Passive buzzer requires PWM of certain frequency to control, so you need to create a software PWM pin through softToneCreate (buzzerPin). The way to create PWM is also introduced before in the sections about BreathingLED and RGBLED.

```
def setup():
    global p
    GPIO.setmode(GPIO.BOARD)      # Use PHYSICAL GPIO Numbering
    GPIO.setup(buzzerPin, GPIO.OUT) # set RGBLED pins to OUTPUT mode
    GPIO.setup(buttonPin, GPIO.IN, pull_up_down=GPIO.PUD_UP)   # Set buttonPin to INPUT
    mode, and pull up to HIGH level, 3.3V
    p = GPIO.PWM(buzzerPin, 1)
    p.start(0);
```

In the while loop of main function, when the button is pressed, subfunction alertor() will be called and the alertor will issue a warning sound. The frequency curve of the alarm is based on the sine curve. We need to calculate the sine value from 0 to 360 degree and multiply a certain value (here is 500) and plus the resonant frequency of buzzer. We can set the PWM frequency through p.ChangeFrequency(toneVal).

```
def alertor():
    p.start(50)
    for x in range(0, 361):
        sinVal = math.sin(x * (math.pi / 180.0))
        toneVal = 2000 + sinVal * 500
        p.ChangeFrequency(toneVal)
        time.sleep(0.001)
```

When the button is released, the buzzer will be closed.

```
def stopAlertor():
    p.stop()
```

# Chapter 7 WebIOPi & IOT

In this chapter, we will learn how to use GPIO to control RPi through remote network and how to build a WebIOPi service on the RPi.

“IOT” is Internet of Things. The development of IOT will greatly change our habits and make our lives more convenient and efficient.

“WebIOPi” is the Raspberry Pi Internet of Things Framework. After configuration for WebIOPi on your RPi is completed, you can use web browser on mobile phones, computers and other equipments to control, debug and use RPi GPIO conveniently. It also supports many commonly used communication protocol, such as serial, I2C, SPI, etc., and a lot of equipments, like AD/DA converter pcf8591 used before and so on. Then on this basis, through adding some peripheral circuits, you can create your own smart home.

For more details about WebIOPi, please refer to: <http://webiopi.trouch.com/>

## Project 7.1 Remote LED

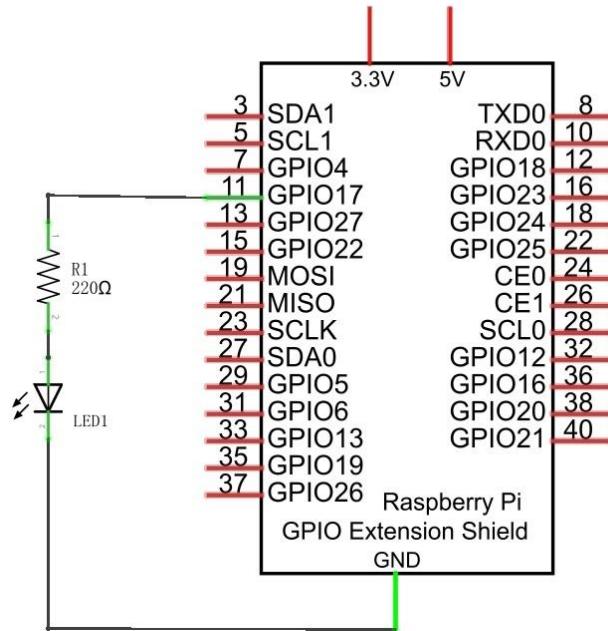

In this experiment, we need build a WebIOPi service, and then control the RPi GPIO to control a LED through Web browser of phone or PC.

### Component List

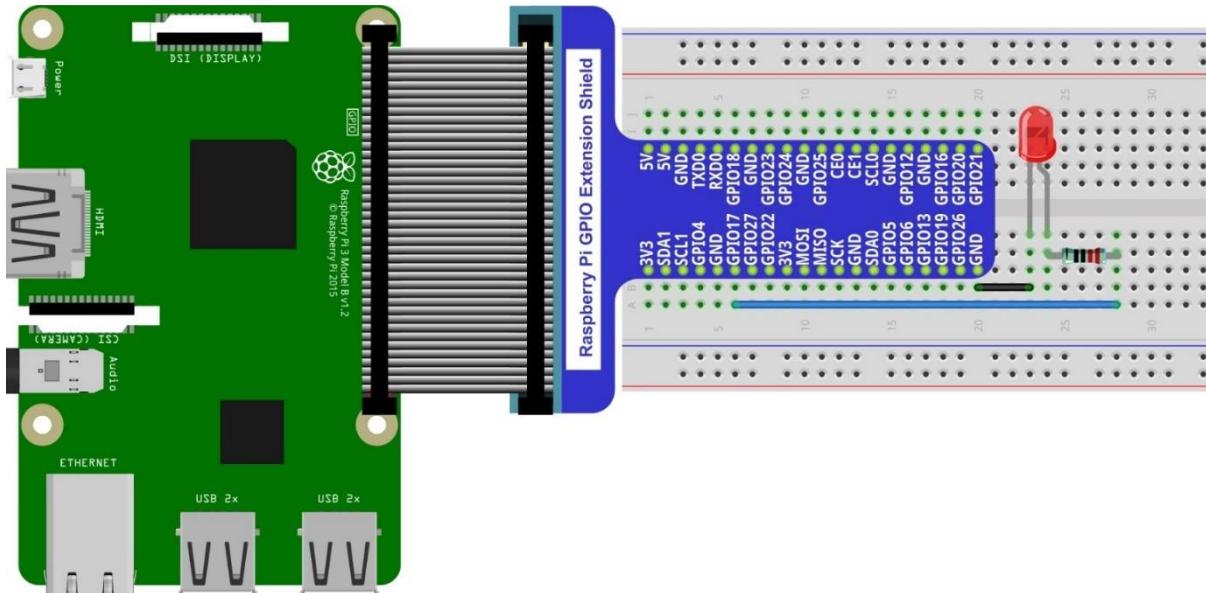

Raspberry Pi (with 40 GPIO) x1 GPIO Extension Board & Wire x1 BreadBoard x1	LED x1	Resistor 220Ω x1
Jumper M/M x2 		

## Circuit

Schematic diagram

Hardware connection. If you need any support, please feel free to contact us via: [support@freenove.com](mailto:support@freenove.com)

## Build WebIOPi Service Framework

The following is the key part of this chapter. The installation steps refer to WebIOPi official. And you also can directly refer to the official installation steps. The latest version (until 2016-6-27) WebIOPi is 0.7.1. So, you may have some problems in use. We will explain these problems and provide the solution in the following installation steps.

Here are the steps to build WebIOPi:

### Installation

1. Get the installation package. You can use the following command to obtain.

```
 wget https://github.com/Freenove/WebIOPi/archive/master.zip -O WebIOPi.zip
```

2. Extract the package and generate a folder named "WebIOPi-master". Then enter the folder.

```
 unzip WebIOPi.zip
```

```
 cd WebIOPi-master/WebIOPi-0.7.1
```

3. Patch for Raspberry Pi B+, 2B, 3B, 3B+.

```
 patch -p1 -i webiopi-pi2bplus.patch
```

4. Run setup.sh to start the installation, and the process need a period of time to wait.

```
 sudo ./setup.sh
```

5. If setup.sh does not have permission to execute, execute the following command

```
 sudo sh ./setup.sh
```

### Run

After the installation is completed, you can use the webiopi command to start running.

```
$ sudo webiopi [-h] [-c config] [-l log] [-s script] [-d] [port]
```

Options:

<b>-h, --help</b>	Display this help
<b>-c, --config file</b>	Load config from file
<b>-l, --log file</b>	Log to file
<b>-s, --script file</b>	Load script from file
<b>-d, --debug</b>	Enable DEBUG

Arguments:

port	Port to bind the HTTP Server
------	------------------------------

For instance, to start with verbose output and the default config file :

```
 sudo webiopi -d -c /etc/webiopi/config
```

The Port is 8000 in default.

Until now, WebIOPi has been launched, and you can press "Ctrl+C" to terminate service.

### Access WebIOPi over local network

Under the same network, use mobile phone or PC browser to open your RPi IP address, and add port number like 8000. For example, my raspberry pi IP address is 192.168.1.109. Then, in the browser, should input:

<http://192.168.1.109:8000/>

**Default user is "webiopi" and password is "raspberry".**

Then, enter the main control interface:

# WebIOPi Main Menu

## GPIO Header

Control and Debug the Raspberry Pi GPIO with a display which looks like the physical header.

## GPIO List

Control and Debug the Raspberry Pi GPIO ordered in a single column.

## Serial Monitor

Use the browser to play with Serial interfaces configured in WebIOPi.

## Devices Monitor

Control and Debug devices and circuits wired to your Pi and configured in WebIOPi.

Click on GPIO Header to enter the GPIO control interface.

3.3V	1	2	5.0V	
I2C SDA	3	4	5.0V	
I2C SCL	5	6	GROUND	
ONEWIRE	7	8	UART TX	
GROUND	9	10	UART RX	
OUT	GPIO 17	11	12	GPIO 18 IN
IN	GPIO 27	13	14	GROUND
IN	GPIO 22	15	16	GPIO 23 IN
	3.3V	17	18	GPIO 24 IN
ALTO	GPIO 10	19	20	GROUND
ALTO	GPIO 9	21	22	GPIO 25 IN
ALTO	GPIO 11	23	24	GPIO 8 OUT
GROUND	25	26	GPIO 7	OUT
--	27	28	--	
IN	GPIO 5	29	30	GROUND
IN	GPIO 6	31	32	GPIO 12 IN
IN	GPIO 13	33	34	GROUND
IN	GPIO 19	35	36	GPIO 16 IN
IN	GPIO 26	37	38	GPIO 20 IN
GROUND	39	40	GPIO 21	IN

Control methods:

- Click/Tap the OUT/IN button to change GPIO direction.
- Click/Tap pins to change the GPIO output state.

#### Completed

According to the circuit we build, set GPIO17 to OUT, then click Header11 to control the LED.

## About WebIOPi

( If you are using raspberry pie 4B, you may have some trouble. We will also finish the WebIOPi adaptation to raspberry 4B as soon as possible, and update it at the first time. )

The reason for changing file in the configuration process is that the model of new generation of RPi CPU is different from old one, which result in some of the issues during using.

WebIOPi has not provide corresponding installation package for latest RPi timely. Therefore, there are two changes in the configuration, and some BUG may exist to cause some problems to WebIOPi function. We look forward to that the author of WebIOPi to provide a complete set of the latest version of installation package to fit with RPi. WebIOPi can achieve far more than this, so we also look forward to learning and exploring with the funs.

## What's next?

Thanks for your reading.

This tutorial is all over here. If you find any mistakes, omissions or you have other ideas and questions about contents of this tutorial or the kit and etc, please feel free to contact us: [support@freenove.com](mailto:support@freenove.com)  
We will check and correct it as soon as possible.

If you are interesting in processing, you can learn the Processing.pdf in the unzipped folder.

If you want to learn more about Arduino, Raspberry Pi, smart cars, robots and other interesting products in science and technology, please continue to focus on our website. We will continue to launch cost-effective, innovative and exciting products.

<http://www.freenove.com/>

Thank you again for choosing Freenove products.

## Warning

When you purchase or use Freenove basic Starter Kit for Raspberry Pi, please note the following:

- This product contains small parts. Swallowing or improper operation can cause serious infections and death. Seek immediate medical attention when the accident happened.
- Do not allow children under 3 years old to play with or near this product. Please place this product in where children under 3 years of age cannot reach.
- Do not allow children lack of ability of safe to use this product alone without parental care.
- Never use this product and its parts near any AC electrical outlet or other circuits to avoid the potential risk of electric shock.
- Never use this product near any liquid and fire.
- Keep conductive materials away from this product.
- Never store or use this product in any extreme environments such as extreme hot or cold, high humidity and etc.
- Remember to turn off circuits when not in use this product or when left.
- Do not touch any moving and rotating parts of this product while they are operating.
- Some parts of this product may become warm to touch when used in certain circuit designs. This is normal. Improper operation may cause excessively overheating.
- Using this product not in accordance with the specification may cause damage to the product.

## About

Freenove is an open-source electronics platform. Freenove is committed to helping customer quickly realize the creative idea and product prototypes, making it easy to get started for enthusiasts of programing and electronics and launching innovative open source products. Our services include:

- Electronic components and modules
- Learning kits for Arduino
- Learning kits for Raspberry Pi
- Learning kits for Technology
- Product customization service
- Robot kits
- Auxiliary tools for creations

Our code and circuit are open source. You can obtain the details and the latest information through visiting the following web sites:

<http://www.freenove.com>

<https://github.com/freenove>

Your comments and suggestions are warmly welcomed, and please send them to the following email address:  
[support@freenove.com](mailto:support@freenove.com)

If you have any business matters, please feel free to contact us:
